Index—California and Western Medicine, Volume 45
July to December, 1936

INDEX ARRANGEMENT

Sequence of Subheads in Index

This index is arranged under the following headings:

I. Authors.
II. Subjects—Titles of papers.
III. Editorials.
IV. Editorial Comment articles.
V. Bedside Medicine articles.
VI. Medical History articles.
VII. Miscellany columns.
VIII. California Medical Association.
  (a) General
  (b) Component County Societies.
  (c) Department of Public Relations.
  (d) Woman's Auxiliary.
IX. Deceased Members.
X. Book Reviews.
XI. Report of Medical Examiners.

* * *

Key to Abbreviations in This Index

Or.—Original Article.
C. R.—Case Report.
B. M.—Bedside Medicine.
Ed.—Editorial.
E. C.—Editorial Comment.
C. N.—Clinical Notes.
L. M. H.—Lure of Medical History.

Index to Pages, Volume 45, California and Western Medicine, July to December, 1936

Date of Issue	No. of Pages	Date of Issue	No. of Pages
July, 1936	1-112	October, 1936	305-376
August, 1936	113-216	November, 1936	377-448
September, 1936	217-304	December, 1936	449-520

* * *

Two Volumes Yearly

California and Western Medicine is annually issued in two volumes: the first, from January to June, inclusive; and the second from July to December, inclusive.

* * *

American Medical Association Quarterly Cumulative Index

Memers who wish to consult a general medical index are referred to the Quarterly Cumulative Index of the American Medical Association.

I

AUTHORS—INDEX

PAGE

A

Abowitz, Jacob—Pathologic Findings at the Pars Cardia of the Stomach (Or.) 255
Allington, H. V., and Templeton, H. J.—Scabicidal Drugs: An Experimental Study (Or.) 487
Anderson, Nelson Paul, and Ayres, Samuel, Jr.—Pyodermatoses (Or.) 243
Atkinson, R. C.—Relapsing Fever (C. R.) 172
Ayres, Samuel, Jr., and Anderson, Nelson Paul—Pyodermatoses (Or.) 243

B

Bancroft, Irving—Radium in Lesions of the Face (C. N.) 496
Barkan, Hans—Ocular Syphilis: Its Treatment (Or.) 13
Baumgartner, Conrad J.—Ruptured Appendix in Children: Its Management (Or.) 51
Behneman, H. M. F.—Electrocardiography: Its Value to the General Practitioner (Or.) 158
Bennett, Dudley W.—Venous Pressure (E. C.) 381
Bierman, Jessie M.—A Mediastinal Tumor (C. R.) 423
Binkley, R. W., and Cole, E. R.—Gunshot Wounds of the Abdomen (Or.) 26
Birnbaum, Walter, Brown, Maurice, and Rhodes, George K.—Acute Appendicitis (Or.) 458
Bliss, Guy L.—Disorders of Sleep in Children (B. M.) 67
Bogen, Emil, and Loomis Russell N.—Poisoning Poisonous Spiders (Or.) 31
Bogen, Emil—Irritant Factors in Tobacco Smoke (Or.) 342
Bolin, Zera E.—Cancer Clinics in Small Hospitals (Or.) 409
Bowers, Albert G.—Scarlet Fever (B. M.) 284
Breyer, John H.—Thrombosis and Embolism: Preoperative and Postoperative Care in Their Prevention (Or.) 463
Brown, Maurice, Rhodes, George K., and Birnbaum, Walter—Acute Appendicitis (Or.) 458
Burmester, Ben R.—Reticulocytes: Their Color, Volume, and Saturation Indices (E. C.) 119

C

Callander, C. Latimer—Amputation of the Thigh (Or.) 252
Cleary, Ernest W.—Hammer-Toe (B. M.) 177
Cleary, E. W., and Morrison, Gordon M.—A Self-Released Lock-Bolt for Fractures of the Femoral Neck (C. N.) 279
Cochran, George A.—The Medical Management of Peptic Ulcer (Or.) 339
Coffey, Ermanell C., and Coffey, Stanley E.—Unusual Case of Fibromyoma Uteri (C. R.) 355
Coffey, Stanley E., and Coffey, Ermanell C.—Unusual Case of Fibromyoma Uteri (C. R.) 355
Cole, E. R., and Binkley, R. W.—Gunshot Wounds of the Abdomen (Or.) 26
Cook, Sherburne F.—California's First Medical Survey: Report of Surgeon-General José Benites (L. M. H.) 352
Cooke, A. B.—The Physician and the Drug Trade (E. C.) 4
Crabtree, Winston C.—Rhinophyma (Or.) 485
Cross, W. W.—Urinary Retention (B. M.) 500

D

Daniel, William H.—Cancer of the Rectum (Or.) 161
Dillon, James R.—Urinary Tract Infection with "Clear Urine" (Or.) 489
Doughty, J. F.—Amebiasis: Its Diagnosis by the General Practitioner (C. R.) 64
Drury, Douglas R.—The Liver and Carbohydrate Metabolism (Or.) 45

E

Ebaugh, Franklin G.—Sleep Disorders in Clinical Practice (Or.):
    Part I 5
    Part II 128
Eder, Lawrence F.—Cancer of the Fundus Uteri (B. M.) 361
Edler, William—Fallacious Trends in Psychiatry (Or.) 412
Ely, Leonard W.—Hammer-Toe (B. M.) 177
Epstein, Norman N., Simpson, Roger G., and Miller, Hiram E.—Mapharsen: Its Use in the Treatment of Syphilis (Or.) 321

F

Findlay, Francis M.—Hypertension: Its Surgical Approach (Or.) 334
Frawley, J. M.—Whooping Cough: Its Prophylaxis and Treatment (Or.) 467
Friedlander, R. D., and Underwood, F. J.—Interpretation of Electrocardiograms (E. C.) 223

G

Gay, LeRoy K., and Hardesty, J. T.—Tests for Vasomotor Control (Or.) 331
Gebhardt, L. P., and Schultz, E. W.—Chemoprophylaxis of Poliomyelitis (Or.) 138
Gibson, Thomas E.:
    The Present Status of Renal Sympathectomy (Or.) 10
    Urinary Retention (B. M.) 498
Girard, Frank R.—Treatment of Hernia by the Injection Method (Or.) 385
Goeckerman, William H.:
    Latent Syphilis (Or.) 55
    Dermatology—Some Thoughts on Its Future (Or.) 227
Gundrum, F. F., and Zimmerman, Harold—Multiple Cysts of Both Lungs (C. R.) 61

H

Haldeman, Keene O., and Soto-Hall, Ralph—Bilateral Dislocations of the Cervical Spine (Or.) 238
Hanzlik, Harold—Medical Conditions, Practices, and Foundations in the Continental Colonies (L. M. H.):
    Part I 169
    Part II 275
Hardesty, J. T., and Gay, LeRoy K.—Tests for Vasomotor Control (Or.) 331
Harrington, David O.—Practical Quantitative Perimetry (Or.) 473
Harris, Franklin I., and White, Alfred S.:
    Injection Treatment of Hernia: Its Experimental Basis (Or.) 382
    Injection Treatment of Hernia: Its Present-Day Status (Or.) 391
Herring, James B.—Heat-Producing Appliances: Their Comparative Value in the Treatment of Prostatic Infections (Or.) 140
Hoag, Carl L.—A New Approach to Resection of Cancer of the Colonic Flexures (Or.) 148
Hoffman, Paul E.—Cancer of the Fundus Uteri (B. M.) 360
Hunt, Verne C.—Cancer of the Fundus Uteri (B. M.) .. 362

I

Ingham, Samuel D.—Apraxia (Or.) 229

J

Johnson, Clark M.—Caudal and Transsacral Anesthesia (Or.) 48
Jones, O. W., Jr., and Naffziger, Howard C.—Tumors on the Spinal Cord: Their Diagnosis (Or.) 17

K

Kerr, William J.—Cardiac Murmurs (E. C.) 311
Kerr, William J., and Noble, C. A., Jr.—New Sign Found in Transverse Lesions of Spinal Cord (Or.) 346
Kilbourne, Norman J.—Phlebitis: Its Treatment (C. N.) 176
Kliman, F. E., and Lazard, E. M.—Traumatic Rupture of the Uterus in Advanced Pregnancy (Or.) 482

L

Lagen, John B.—The Technique of Electrocardiography (E. C.) 222
Lamb, Edward J.—Scarlet Fever (B. M.) 285

PAGE
Larsen, Albert E.—A Medical Survey of One Thousand Work Relief Persons (Or.) 317
Lazard, E. M., Kliman, F. E.—Traumatic Rupture of the Uterus in Advanced Pregnancy (Or.) 482
Leake, Chauncey D.:
  Chronic Vitamin D Toxicity (E. C.) 311
  Practica Medici Moderni (Or.) 455
Longley, E. G., Potter, James E., and Redewill, Francis H.—Hyperpyrexia: As an Adjunct in the Treatment of Cerebrospinal and Kahn-Fast Syphilis (Or.) 402
Loomis, Russell N., and Bogen, Emil—Poisoning Poisonous Spiders (Or.) 31

M

Magee, H. Ross—Treatment of Exophthalmic Goiter (Or.) 257
Marquis, H. H., Noble, C. A., Jr., and Perry, I. H.—Hepatic Cirrhosis with Encapsulated Peritonitis (C. R.) 172
Marshall, Harold K., and Thompson, Robert H.—Mortality Lessons in a Series of 4,029 Gynecologic Operations (Or.) 263
Marshall, O. C.—Acriflavine and Liver Damage, with a Report of a Fatality Associated with Its Use (C. R.) 356
Martin, Harry W.—Urinary Retention (B. M.) 499
Mathews, Samuel S.—Hammer-Toe (B. M.) 177
McClendon, S. J.—Pediatrics: Some Present-Day Trends (Or.) 125
Meyer, A. W.—The Hunters in Embryology (L. M. H.)
  Part I 420
  Part II 492
Miller, Hiram E., Epstein, Norman N., and Simpson, Roger G.—Mapharsen: Its Use in the Treatment of Syphilis (Or.) 321
Montgomery, Douglass W.—Epitheliomata of the Skin (Or.) 134
Morrison, Gordon M., and Cleary, E. W.—A Self-Released Lock-Bolt for Fractures of the Femoral Neck (C. N.) 279

N

Naffziger, Howard C., and Jones, O. W., Jr.—Tumors on the Spinal Cord: Their Diagnosis (Or.) 17
Nagel, Gunther W.—Cardiospasm (Or.) 271
Negley, J. C.—Urinary Extravasation (Or.) 38
Newman, William W.—Cardiovascular Syphilis: Its Treatment (Or.) 234
Noble, C. A., Jr., and Kerr, William J.—New Sign Found in Transverse Lesions of Spinal Cord (Or.) 346
Noble, C. A., Jr., Perry, I. H., and Marquis, H. H.—Hepatic Cirrhosis with Encapsulated Peritonitis (C. R.) 172
Novy, Frederick G., Jr.—Sarcoid (Or.) 41

P

Pallette, Edward C.—Portal Thrombosis (Or.) 324
Parsons, H. H.—A Practical Lamp for the Microscope (C. N.) 62
Peers, Robert Stewart—Arthritis: A Medical Problem (Or.) 399
Perry, I. H., Marquis, H. H., and Noble, C. A., Jr.—Hepatic Cirrhosis with Encapsulated Peritonitis (C. R.) 172
Pierson, Philip H.—Silicosis (Or.) 477
Potter, James E., Redewill, Francis H., and Longley, E. G.—Hyperpyrexia: As an Adjunct in the Treatment of Cerebrospinal and Kahn-Fast Syphilis (Or.) 402

R

Redewill, Francis H., Longley, E. G., and Potter, James E.—Hyperpyrexia: As an Adjunct in the Treatment of Cerebrospinal and Kahn-Fast Syphilis (Or.) 402
Reiss, Oscar—Disorders of Sleep in Children (B. M.) 65
Rhodes, George K., Birnbaum, Walter, and Brown, Maurice—Acute Appendicitis (Or.) 458
Rinehart, James F.—Capillary Resistance (E. C.) 453
Robinson, Saul S.—Puerperal Pemphigus (C. R.) 497

PAGE
Rosenblum, Harold—Determination of Blood Velocity by the Sodium Dehydrocholate Method (E. C.) 381

S

Sampson, John J.—The Pulse Pressure—Pulse Rate Exercise Tolerance Test (E. C.) 309
Schultz, E. W., and Gebhardt, L. P.—Chemoprophylaxis of Poliomyelitis (Or.) 138
Settle, Francis B.—Cancer of the Thyroid Gland (Or.) 247
Shaw, E. B.—Scarlet Fever (B. M.) 282
Shelton, E. Kost—Pituitary Growth Factor (Or.) 20
Shepardson, H. Clare:
  Adrenal Endocrinopathies in Childhood (Or.) 153
  Hyperinsulinism-Hypoglycemia (B. M.) 425
Shuman, John W.—Peptic Ulcer (C. R.) 423
Siefert, Alfred C.—Meditations on Some Present-Day Medical Problems (Or.) 348
Simpson, Roger G., Miller, Hiram E., and Epstein, Norman N.—Mapharsen: Its Use in the Treatment of Syphilis (Or.) 321
Singer, J. J.:
  Collapse Therapy in Pulmonary Tuberculosis (Or.) 120
  Tumors and Cysts of the Lung: Diagnostic Methods (Or.) 313
Smith, Bertnard—Clinical Studies with Protamine-Insulin (Or.) 144
Smith, Sydney Kinnear—Psychiatry: Reasonable Essentials for Its Practice (Or.) 132
Soto-Hall, Ralph, and Haldeman, Keene O.—Bilateral Dislocations of the Cervical Spine (Or.) 238
Spiers, H. W.—Fundamental Principles in Fracture Surgery (C. N.) 281
Stafford, Henry E.—Disorders of Sleep in Children (B. M.) 66
Stephenson, Henry A.—Better Obstetrics (Or.) 224

T

Talmage, Carl H.—Double Uterus with Features of Special Interest (C. R.) 280
Taylor, Fletcher B.—Hyperinsulinism-Hypoglycemia (B. M.) 428
Templeton, H. J., and Allington, H. V.—Scabicidal Drugs: An Experimental Study (Or.) 487
Thebaut, Maxwell—Meralgia Paresthetica (C. R.) 174
Thompson, Robert H., and Marshall, Harold K.—Mortality Lessons in a Series of 4,029 Gynecologic Operations (Or.) 263
Thurber, Packard—Athletic Injuries (Or.) 261
Tillotson, Joseph E.—A Simple Abdominal Cup for Controlling Cystotomy Drainage (C. R.) 358
Truman, Stanley R.—Narcolepsy (C. R.) 63

U

Underwood, F. J., and Friedlander, R. D.—Interpretation of Electrocardiograms (E. C.) 223

V

Van Nostrand, John J.—Court Decision on Chiropractic Case (Or.) 419

W

Webb, U. S.—Therapeutic Scope of Chiropractic: A Legal Brief (Or.) 414
White, Alfred S., and Harris, Franklin I.:
  Injection Treatment of Hernia: Its Experimental Basis (Or.) 382
  Injection Treatment of Hernia: Its Present-Day Status (Or.) 391
Widney, Joseph P.—Rational or Liberal Medicine (L. M. H.): Part II 58
Wilson, Harry H.—The Management of Alcoholism (Or.) 349
Wright, La Verne—Obstetrical Anesthesia (Or.) 328

Z

Zimmerman, Harold, and Gundrum, F. F.—Multiple Cysts of Both Lungs (C. R.) 61
Ziskind, Eugene—Hyperinsulinism-Hypoglycemia (B. M.) 427

II

SUBJECTS—INDEX

A

Acriflavine and Liver Damage, with a Report of a Fatality Associated with Its Use—O. C. Marshall (C. R.) 356
Acute Appendicitis—George K. Rhodes, Walter Birnbaum, and Maurice J. Brown (Or.) 458
Adrenal Endocrinopathies in Childhood—H. Clare Shepardson (Or.) 153
Alcoholism, The Management of—Harry H. Wilson (Or.) 349
Amebiasis: Its Diagnosis by the General Practitioner—J. F. Doughty (C. R.) 64
Amputation of the Thigh—C. Latimer Callander (Or.) 252
Anesthesia—Caudal and Transsacral—Clark M. Johnson (Or.) 48
Annual Report of the Rockefeller Foundation for the Year 1935 (Ed.) 220
Apraxia—Samuel D. Ingham (Or.) 229
Are Physicians Remiss in Civic Responsibilities? (Ed.) 217
Arthritis—A Medical Problem—Robert Stewart Peers (Or.) 399
Athletic Injuries—Packard Thurber (Or.) 261
"Attack on Group Medicine, The" (Ed.) 219
Automobile Accidents and "Vehicides": Some Federal and California Statistics (Ed.) 307

B

Better Obstetrics—Henry A. Stephenson (Or.) 224
Bilateral Dislocations of the Cervical Spine—Ralph Soto-Hall and Keene O. Haldeman (Or.) 238

C

California's First Medical Survey: Report of Surgeon-General José Benites—Sherburne F. Cook (L. M. H.) 352
Cancer Clinics in Small Hospitals—Zera E. Bolin (Or.) 409
Cancer of the Colonic Flexures, A New Approach to Resection of—Carl L. Hoag (Or.) 148
Cancer of the Fundus Uteri—Paul E. Hoffmann, Lawrence F. Eder and Verne C. Hunt (B. M.) 360
Cancer of the Rectum—William H. Daniel (Or.) 161
Cancer of the Thyroid Gland—Francis B. Settle (Or.) 247
Capillary Resistance—James F. Rinehart (E. C.) 453
Cardiac Murmurs—William J. Kerr (E. C.) 311
Cardiospasm—Gunther W. Nagel (Or.) 271
Cardiovascular Syphilis: Its Treatment—William W. Newman (Or.) 234
Caudal and Transsacral Anesthesia—Clark M. Johnson (Or.) 48
Chemoprophylaxis of Poliomyelitis—E. W. Schultz and L. P. Gebhardt (Or.) 138
Chiropractic: A Legal Opinion on Its Therapeutic Scope (Ed.) 380
Chronic Vitamin D Toxicity—Chauncey D. Leake (E. C.) 311
Clinical Studies with Protamine-Insulin—Bertnard Smith (Or.) 144
Collapse Therapy in Pulmonary Tuberculosis—J. J. Singer (Or.) 120
Constitution and By-Laws of the California Medical Association: A New and Revised Edition (Ed.) 118
Coronado Annual Session of 1936 (Ed.) 1

PAGE
Councilor District Medical Societies: Shall California Organize Them? (Ed.) 451
Court Decision on Chiropractic Case—John J. Van Nostrand (Or.) 419

D

Death of Dr. Campbell P. Howard, Guest Speaker at the Coronado Annual Session (Ed.) 4
Del Monte Annual Session, May 2-5, 1937: Papers for Scientific Program Should Be Started Now (Ed.) 115
Dermatology—Some Thoughts on Its Future—William H. Goeckerman (Or.) 227
Determination of Blood Velocity by the Sodium Dehydrocholate Method—Harold Rosenblum (E. C.) 381
Disorders of Sleep in Children—Oscar Reiss, Henry E. Stafford, and Guy L. Bliss (B. M.) 65
Double Uterus with Features of Special Interest—Carl H. Talmage (C. R.) 280

E

Electrocardiography: Its Value to the General Practitioner—H. M. F. Behneman (Or.) 158
Epitheliomata of the Skin—Douglass W. Montgomery (Or.) 134
Escamilla, Roberto F.—Vital Capacity Determination: With Particular Reference to Its Value in Heart Disease (E. C.) 453
Exophthalmic Goiter, Treatment of—H. Ross Magee (Or.) 257

F

Fallacious Trends in Psychiatry—William Edler (Or.) 412
Fall Program Time for County Societies (Ed.) 308
Federal Social Security Program: Some Interesting Facts (Ed.) 116
Fibromyoma Uteri, Unusual Case of — Stanley E. Coffey and Ermanell C. Coffey (C. R.) 355
Fracture Surgery, Fundamental Principles in—H. W. Spiers (C. R.) 281
Fundamental Principles in Fracture Surgery—H. W. Spiers (C. R.) 281

G

Gunshot Wounds of the Abdomen—R. W. Binkley and E. R. Cole (Or.) 26
Gynecologic Operations, Mortality Lessons in a Series of 4,029—Harold K. Marshall and Robert H. Thompson (Or.) 263

H

Hammer-Toe—Leonard W. Ely, Samuel S. Mathews, and Ernest W. Cleary (B. M.) 177
Harrison Narcotic Law (Ed.) 115
Harrison Narcotic Law—Decision of the District Court of the United States in: U. S. A., Plaintiff, vs. Edward H. Anthony, Defendant (Or.) 164
Heat-Producing Appliances: Their Comparative Value in the Treatment of Prostatic Infections—James B. Herring (Or.) 140
Hernia by the Injection Method, Treatment of—Frank R. Girard (Or.) 385
Hepatic Cirrhosis with Encapsulated Peritonitis—C. A. Noble, Jr., I. H. Perry, and H. H. Marquis (C. R.) 172
Hospital Service in the United States, On (Ed.) 378
Hospitalization Plans in California (Ed.) 449
Hunters in Embryology, The—A. W. Meyer (L. M. H.):
  Part I 420
  Part II 492
Hyperinsulinism-Hypoglycemia—H. Clare Shepardson, Eugene Ziskind, and Fletcher B. Taylor (B. M.) 425
Hyperpyrexia: As an Adjunct in the Treatment of Cerebrospinal and Kahn-Fast Syphilis—James E. Potter, Francis H. Redewill, and E. G. Longley (Or.) 402
Hypertension: Its Surgical Approach — Francis M. Findlay (Or.) 334

I

Injection Treatment of Hernia: Its Experimental Basis—Franklin I. Harris and Alfred S. White (Or.) 382
Injection Treatment of Hernia: Its Present-Day Status —Franklin I. Harris and Alfred S. White (Or.) 391
Interpretation of Electrocardiograms—R. D. Friedlander and F. J. Underwood (E. C.) 223
Irritant Factors in Tobacco Smoke—Emil Bogen (Or.) 342

L

Latent Syphilis—William H. Goeckerman (Or.) 55
Liver and Carbohydrate Metabolism, The—Douglas R. Drury (Or.) 45

M

Management of Alcoholism, The—Harry H. Wilson (Or.) 349
Mapharsen: Its Use in the Treatment of Syphilis—Hiram E. Miller, Norman N. Epstein, and Roger G. Simpson (Or.) 321
Mediastinal Tumor, A—Jessie M. Bierman (C. R.) 423
Medical Conditions, Practices, and Foundations in the Continental Colonies—Harold Hanzlik (L. M. H.):
  Part I 169
  Part II 275
Medical Management of Peptic Ulcer, The—George A. Cochran (Or.) 339
Medical Survey on One Thousand Work Relief Persons, A—Albert E. Larsen (Or.) 317
Meditations on Some Present-Day Medical Problems—Alfred C. Siefert (Or.) 348
Meralgia Paresthetica—Maxwell Thebaut (C. R.) 174

PAGE
Mortality Lessons in a Series of 4,029 Gynecologic Operations—Harold K. Marshall and Robert H. Thompson (Or.) 263
Multiple Cysts of Both Lungs—F. F. Gundrum and Harold Zimmerman (C. R.) 61

N

Narcolepsy—Stanley R. Truman (C. R.) 63
New Approach to Resection of Cancer of the Colonic Flexures, A—Carl L. Hoag (Or.) 148
New Legislative Problem: Possible Danger to California State Medical Practice Act, A (Ed.) 305
New Sign Found in Transverse Lesions of Spinal Cord—William J. Kerr and C. A. Noble, Jr. (Or.) 346

O

Obstetrical Anesthesia—La Verne Wright (Or.) 328
Ocular Syphilis: Its Treatment—Hans Barkan (Or.) 13

P

"Pacific Coast Abortion Ring" (Ed.) 380
Pathologic Findings at the Pars Cardia of the Stomach—Jacob Abowitz (Or.) 255
Pediatrics: Some Present-Day Trends—S. J. McClendon (Or.) 125
Peptic Ulcer—John W. Shuman (C. R.) 423
Peptic Ulcer, The Medical Management of—George A. Cochran (Or.) 339
Perimetry, Practical Quantitative—David O. Harrington (Or.) 473
Phlebitis: Its Treatment—Norman J. Kilbourne (C. N.) 176
Physician and the Drug Trade, The—A. B. Cooke (E. C.) 4
Pituitary Growth Factor—E. Kost Shelton (Or.) 20
Poisoning Poisonous Spiders—Emil Bogen and Russell N. Loomis (Or.) 31
Portal Thrombosis—Edward C. Pallette (Or.) 324
Practical Lamp for the Microscope, A—H. H. Parsons (C. N.) 62
Practical Quantitative Perimetry—David O. Harrington (Or.) 473
Practica Medici Moderni—Chauncey D. Leake (Or.) 455
Practice of Anesthesia: California Supreme Court Denies Application for Rehearing (Ed.) 4
Present Status of Renal Sympathectomy, The—Thomas E. Gibson (Or.) 10
Proposed Initiative Law to Open County Hospitals in California to Non-Indigent Patients Will Not Be on the State Election Ballot in November (Ed.) 113
Protamine-Insulin, Clinical Studies with—Bertrand Smith (Or.) 144
Psychiatry, Fallacious Trends in—William Edler (Or.) 412
Psychiatry: Reasonable Essentials for Its Practice—Sydney Kinnear Smith (Or.) 132
Puerperal Pemphigus—Saul S. Robinson (C. R.) 497
Pulmonary Tuberculosis, Collapse Therapy in—J. J. Singer (Or.) 120
Pulse Pressure—Pulse Rate Exercise Tolerance Test, The—John J. Sampson (E. C.) 309
Pyodermatoses—Nelson Paul Anderson and Samuel Ayres, Jr. (Or.) 243

Q

Qualifying Certificate (Basic Science Legislation) (Ed.) 218

R

Radium in Lesions of the Face—Irving Bancroft (C. N.) 496
Rational or Liberal Medicine—Joseph P. Widney (L. M. H.): Part II 58
Rational or Non-Sectarian Medicine: Doctor Widney's Analysis of Sectarian Medicine, Made Fifty Years Ago, Still Applies in California (Ed.) 117
Relapsing Fever—R. C. Atkinson (C. R.) 172
Renal Sympathectomy, The Present Status of—Thomas E. Gibson (Or.) 10
Reticulocytes: Their Color, Volume, and Saturation Indices—Ben R. Burmester (E. C.) 119
Rhinophyma—Winston C. Crabtree (Or.) 485
Ruptured Appendix in Children: Its Management—Conrad J. Baumgartner (Or.) 51
Rupture of the Uterus in Advanced Pregnancy, Traumatic—E. M. Lazard and F. E. Kliman (Or.) 482

S

"San Fernando Plan" of Los Angeles County: Its Efficiency in the Out-Patient Medical Care of Indigent Citizens (Ed.) 377
Sarcoid—Frederick G. Novy (Or.) 41
Scabicidal Drugs: An Experimental Study—H. J. Templeton and H. V. Allington (Or.) 487
Scarlet Fever—E. B. Shaw, Albert G. Bowers, and Edward J. Lamb (B. M.) 282
Season's Greetings, The (Ed.) 449
Self-Released Lock-Bolt for Fractures of the Femoral Neck—E. W. Cleary and Gordon M. Morrison (C. N.) 279
Silicosis—Philip H. Pierson (Or.) 477
Simple Abdominal Cup for Controlling Cystotomy Drainage, A—Joseph E. Tillotson (C. R.) 358
Sleep Disorders in Clinical Practice—Franklin G. Ebaugh (Or.):
  Part I 5
  Part II 128
State Association Dues (Ed.) 452
Summer Committee Work in County Societies—Preparation of Fall Programs: Collection of County Society Historical Material (Ed.) 3

T

Technique of Electrocardiography, The—John B. Lagen (E. C.) 222

PAGE
Tests for Vasomotor Control—LeRoy K. Gay and J. T. Hardesty (Or.) 331
Therapeutic Scope of Chiropractic: A Legal Brief (Or.) 414
Thrombosis and Embolism: Preoperative and Postoperative Care in Their Prevention—John H. Breyer (Or.) 463
Transverse Lesions of Spinal Cord, New Sign Found in—William J. Kerr and C. A. Noble, Jr. (Or.) 346
Traumatic Rupture of the Uterus in Advanced Pregnancy—E. M. Lazard and F. E. Kliman (Or.) 482
Treatment of Exophthalmic Goiter—H. Ross Magee (Or.) 257
Treatment of Hernia by the Injection Method—Frank R. Girard (Or.) 385
Tumors and Cysts of the Lung: Diagnostic Methods—J. J. Singer (Or.) 313
Tumors on the Spinal Cord: Their Diagnosis—O. W. Jones, Jr., and Howard C. Naffziger (Or.) 17

PAGE
U
Unusual Case of Fibromyoma Uteri—Stanley E. Coffey and Ermanell E. Coffey (C. R.) 355
Urinary Extravasation—J. C. Negley (Or.) 38
Urinary Retention—Thomas E. Gibson, Harry W. Martin, and W. W. Cross (B. M.) 498
Urinary Tract Infection with "Clear Urine"—James R. Dillon (Or.) 489

V
Venous Pressure—Dudley W. Bennett (E. C.) 381
Vital Capacity Determination: With Particular Reference to Its Value in Heart Disease—Roberto F. Escamilla (E. C.) 453

W
Whooping Cough: Its Prophylaxis and Treatment—J. M. Frawley (Or.) 467

THE Exhibit of the Rhythm Foundation at the California Medical Association Convention at Coronado, May 25-28, was one of the best attended of all the Exhibits.

The great interest of the Medical Profession in the Ogino-Knaus Theory of Birth Regulation is indicated by the fact that several thousand Rhythm Pamphlets were distributed at the Convention, several hundred Rhythm Calculators were sold to doctors, and orders were taken for several hundred books, "Conception Period of Women," by Dr. K. Ogino.

Letters of comment are being received from doctors daily, and clinical work is being sponsored with the help and coöperation of the medical profession.

Any information or comments you desire to send the Foundation will be appreciated. The Foundation in return will provide you with all available information upon your request.

Committee on Public Relations

The Committee on Public Relations consists of the chairmen of the following standing committees and of certain general officers of the Association, all serving ex officio. The chairman of the committee is Charles A. Dukes, the secretary is Frederick C. Warnshuis. The director of the Department of Public Relations is Frederick C. Warnshuis. The chairman of the Committee on Public Relations is ex officio a member of the Council.

Fred B. Clarke	Chair., Com. on Health and Public Instruction
Daniel Crosby	Chair., Com. on Hospitals, Dispensaries, Clinics
Morton R. Gibbons	Chair., Com. on Industrial Practice
E. Vincent Askey	Chair., Com. on Membership and Organization
John H. Graves	Chair., Com. on Medical Economics
Junius B. Harris	Chair., Com. on Public Policy and Legislation
Charles A. Dukes	Chair., Cancer Commission
Clarence G. Toland	Chair., Com. on Postgraduate Activities
Edward M. Pallette	President of Califorina Medical Association
Howard Morrow	President-elect
Frederick C. Warnshuis	Secretary-Treasurer

Communications for the Public Relations Department should be addressed to the Director, Frederick C. Warnshuis, M. D., Room 2004, 450 Sutter Street, San Francisco.

Cancer Commission

Charles A. Dukes (Chairman)	Oakland	1937
Lyell C. Kinney (Vice-Chairman)	San Diego	1937
Alson R. Kilgore (Secretary)	San Francisco	1937
Orville Meland (Sec'y for Southern Section)	Los Angeles	1938
A. Herman Zeiler	Los Angeles	1938
Gertrude Moore	Oakland	1938
Harold Brunn	San Francisco	1939
Henry J. Ullmann	Santa Barbara	1939
Clarence G. Toland	Los Angeles	1939

Communications for the Cancer Commission should be addressed to the secretary, A. R. Kilgore, M. D., Room 2004, 450 Sutter Street, San Francisco.

(Roster lists of officers of scientific sections, component county societies, Woman's Auxiliary, A. M. A. delegates, special committees, etc., are continued on advertising pages 4 and 6.)

SUMMER COURSE IN
OPERATIVE SURGERY OF THE ABDOMEN
SEPTEMBER 22 to 30, 1936

Especial attention will be given to the latest development in the surgery of the Stomach, Gall-Bladder, Intestines, Colon, and Rectum. A brief review will be given of surgical anatomy of the various regions, with demonstration on carefully dissected cadavers. The work will consist of lectures, laboratory work on cadavers and fresh human material, and demonstrations and assisting on the living. Fee, $125.

SOUTHERN SIERRAS
SANATORIUM

Food-Handling Methods—Best Safety Assurance.—Most cases of food-poisoning result from careless handling of foods otherwise safe for consumption. Much of this carelessness is found either in the home or in connection with food supplies for outdoor gatherings and in some cases for large and more formal dinners. A recent development in Westchester County, New York, however, was caused by cream puffs, eclairs, and cream pies sold from a White Plains bakery, with the result that 452 serious cases and many of less severity were reported.

Food-poisoning may occur in any season, but summer is the time when greatest vigilance must be exerted. Food spoils in less time, and anything less than perfect refrigeration is potential of danger. As hot weather is at hand, it is time, *now*, to take special precautions to assure the safety of *all* domestic food supplies. In view of these facts, ten rules for food safety, outlined by Mr. L. F. Ey, chief of departmental laboratories, are reëmphasized:

1. To avoid accidental bacterial contamination, all persons engaged in preparing meals for large groups should wash their hands in hot water and soap. The room should be well ventilated and screened.

2. Dishes, utensils and all other ware used must be cleansed in hot soapy water and rinsed with warm running water. It is recommended not to use cloths for drying—air drying is preferable and safer.

3. Use metal ware polishes with precaution.

4. From a sanitary standpoint, refrigeration is one of the best methods of preserving foodstuffs. Therefore, perishable articles should always be kept in a refrigerator, close to freezing temperature.

5. Many foods may be contaminated during the course of preparation. It is of great importance to keep such food at temperatures which will inhibit the growth of bacteria.

6. Wash all vegetables and fruits to remove traces of poisonous chemical sprays.

7. Certain meats should never be eaten raw or insufficiently cooked. Tularemia (rabbit fever) and trichinosis from raw pork are two diseases contracted from eating uncooked, or underdone meat.

8. Use only pasteurized dairy products.

9. No individual or group of volunteer individuals should be permitted to prepare foods for large groups, such as banquets, picnics, church suppers, etc., unless the persons have been trained in the study and prevention of food-poisoning. These requirements include a medical examination by a physician.

10. Finally, if you are a victim of food-poisoning, do not fail to obtain medical aid without delay, and your local health commissioner should also be promptly notified of the situation.

AVAILABLE THROUGH ALL PHARMACIES

EMMENIN

The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.

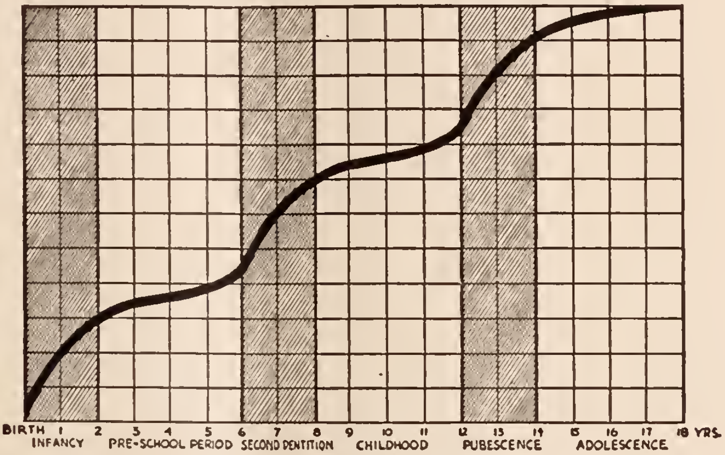
President, Francis P. Wisner, 715 Hart Building, Marysville.
Secretary, Fred W. Didier, Wheatland.

SPEED GROWTH GAINS *with* KARO



CYCLES OF GROWTH FROM BIRTH TO MATURITY

The course of growth from birth to maturity is continuous but rhythmic. This span includes three cycles. The rapid growth in infancy is followed by the slow growth during the pre-school period; the rapid growth during the period of second dentition is followed by the slower growth during childhood; finally, the rapid growth during pubescence is followed by the slower growth during adolescence.

From Kugelmass' "Growing Superior Children", 1935. (Appleton-Century)

How much should a child grow or gain from time to time? That is more significant than mere weight and height measurements. *To the parent* the mark on the wall and the reading on the scale reveal the child's growth. But *to the doctor* deviations from the periodic gains offer a sensitive index of dietary or disease disturbances.

The weight curve in infancy furnishes the most delicate index of progress. The birth weight doubles at five months and trebles at a year. Thereafter gains are slower; six pounds during the second year; five during the third; four during the fourth and fifth years. The trend of the first growth cycle is indicated in the chart.

This pattern of growth repeats itself during childhood and adolescence. Once the growth increments have been determined for a child, his assessment becomes individual and accurate.

When the child fails to gain in weight, high caloric feeding is simplified by reinforcing food with Karo Syrup. If the total caloric intake exceeds the output, the child will gain weight, provided the diet is adequate and chronic disturbances corrected. Every article of diet can be enriched with calories—Karo provides 60 calories per tablespoon. It is relished added to milk, fruit and fruit juices, vegetables, vegetable waters, cereals, breads and desserts. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. SJ-7 17 Battery Pl., New York City

CO-OPERATE WITH YOUR ADVERTISERS

California and Western Medicine, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention California and Western Medicine.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this Journal to members and readers.

A SERVICE AGENCY—FOR READERS

The Journal of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in California and Western Medicine, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. California and Western Medicine and the A. M. A. Service Bureau desire to serve *you*.

THE NEW YORK POLYCLINIC
MEDICAL SCHOOL AND HOSPITAL
(Organized 1881)
(The Pioneer Post-Graduate Medical Institution in America)

PLASTIC REPARATIVE SURGERY

This course includes diagnosis and determination of treatment; pre-operative preparation; anesthesia; operative technique; dressings; post-operative care; with special reference to utilization of the skin and other tissues in correction of disfigurement and replacement of loss, congenital or acquired. Operations on the cadaver. Particular attention is given to lectures, studies and demonstrations of advances in surgical anatomy, pathology, etc., with special reference to the problem actually under consideration.

THORACIC SURGERY

An intensive course. Surgical treatment of chronic suppuration of the lung (pulmonary tuberculosis, abscess of the lung, bronchiectasis) and tumors of the lung. Surgical lesions of the esophagus, heart and diaphragm. Empyemas. Witnessing of operations, cadaver operations, pathologic physiology, experimental surgery and bedside rounds. Indications for surgical treatment, pre-operative care and post-operative management.

MEDICAL EXECUTIVE OFFICER
345 West 50th Street, New York City

Bootlegged Milk a Real Menace—Health Department Regulation Needed.—As milk is a vital factor in sustaining a healthy body, the fact makes it mandatory, in a sense, for those engaged in public health work to call attention regularly to the health hazards that exist with respect to this article of food. To this end, medical journals and public health bulletins frequently publish appropriate notices in which the general public is warned what to do when purchasing milk for the family table. Volumes have been written on the importance of using only pasteurized milk and other dairy products, and while great progress along this line is noted, there is a loophole under present state and city requirements which permits the sale of so-called bootleg milk in many parts of the state, and which, unfortunately, cannot be abated due to lack of centralized legal authority.

It is said that the root of all evil lies in matters dealing with finances; but it is doubtful that this specific menace would continue if fathers and mothers were fully informed of the danger to which they subject their families when they purchase milk from sources that do not come under health department regulation. It is difficult to accept this adage as the real cause under all circumstances; yet it is true that the bootlegged milk business increased during the recent economic depression, and to such a limit in some localities that it is seriously affecting the business of the legitimate and law-abiding dairyman, whose product is inspected and thereby made safe, so far as the public health is concerned.

Specifically, the unguarded sources are dairies with one or two cows, which sell milk near or adjacent to a district where rigid control measures are enforced. Such dealers are found along the main highways or in small country stores, selling raw milk to consumers who drive out to the country to get fresh raw milk, because they believe money is saved and a better product is obtained. A dealer handling a milk supply that is not inspected by the health department may impress his customers with the fact that he has been in the dairy business for many years, and never had any sickness or complaints reported by the users of his supply. What assurance, however, can he give to his trade that his product will always be free from milk-borne infections? Who knows but that on the day of his boasting he may be selling a contaminated supply of milk which is loaded with typhoid or undulant fever organisms, or other infectious organisms transmissible through milk.

Health department records everywhere show, unequivocally, that milk-borne diseases are seldom, if ever, reported from cities and districts where all milk supplies are inspected, pasteurized and approved, but that many outbreaks involving large and small numbers of persons occur, generally in small communities or in the rural areas where raw milk is sold.

One answer in the solution of this problem is obviously that of educating those individuals who for economic or other personal reasons insist upon patronizing the bootlegger of milk. This phase of the problem can best be met by giving the widest kind of unfavorable publicity to the sources from which uninspected milk is being sold in the county. The second and probably most effective way of getting immediate action would be through a state regulation which would cover from a strictly public health department point of view the supervision and inspection of all milk produced and sold in the state; the smallest as well as the largest dairy to be regulated and controlled in an identical manner. Such state regulations, under the State Department of Health, should conform basically with the Standard Milk Ordinance of the United State Public Health Service.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE
(In affiliation with Cook County Hospital)

TEACHING FACULTY–ATTENDING STAFF OF COOK COUNTY HOSPITAL
Address: Registrar, 427 South Honore Street, Chicago, Ill.

Answering a solicitous interrogatory of the ardent believer with an unembroidered and frank "I don't know" should not give offense. On the other hand, such reply, coupled with an "or you either," while possibly true, is superogatory, brusque, and implies discrimination superior to his own.

Burneice Larson, Director), Top Floor, Pittsfield Building, Chicago, Illinois.

Cook Pork Well to Prevent Trichinosis. — Reports received by the Federal Department of Agriculture of several recent cases of illness and some deaths from trichinosis justify a repetition of the warning to cook pork thoroughly before serving. Trichinosis is caused by eating raw or insufficiently cooked pork which contains very small parasites known as trichinae. These parasites occur in a small percentage of hogs, which themselves suffer no apparent inconvenience. But the meat of such hogs, unless yell cooked, constitutes a considerable danger to human health.

The assumption that pork which has passed inspection at a federally inspected establishment is safe even when eaten raw or undercooked is erroneous, department officials state. There is no test that will show definitely whether trichinae are present in a sample of pork, except in some cases of severe infestation. Certain products that are customarily eaten without cooking in the home are given a special processing at federally inspected establishments, and are free from live trichinae. Pork products of the kind that ordinarily are cooked in the home are not processed in meat-packing establishments, since thorough cooking is a complete safeguard.

When infested pork is eaten by human beings in a raw or insufficiently cooked state, the trichinae are set free in the digestive tract, where they give rise to numerous young worms. The latter invade the muscles, thus causing the painful disease, trichinosis, which somewhat resembles typhoid fever, meningitis, and several other diseases that are characterized by fever. Severe cases of this disease are likely to result in death.

The Department of Agriculture has repeatedly cautioned the public to cook pork thoroughly before eating it, and has also given the same warning in pictorial form. A small poster presenting such information has been prepared in both the German and Italian languages as well as in English. A two-color poster suitable for display in meat shops is in course of preparation and will be furnished to interested persons on request. While emphasizing that cooking is a health safeguard, the Department also points out that pork is a savory, nourishing food of excellent nutritive value.

. . . We do not yet sufficiently realize the truth that as, in this life of ours, the physical underlies the mental, the mental must not be developed at the expense of the physical . . .—Herbert Spencer (1860).

The most important quality of education is flexibility. Flexibility is allied to play. Play is the essence of adaptability, and there is no prescribed pattern for it. Opportunities must be used as they come along.—Boyd H. Bode (1932).

NUTRI-AD
ARTHROPHYLL
(6)
A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL (6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL (6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

Medical Science Exhibits. A Century of Progress. Chicago World's Fair, 1933 and 1934. By Eben J. Carey, Sc.D., M.D., Dean Marquette University School of Medicine, Milwaukee, Wisconsin; Chief, Medical Section Hall of Science, A Century of Progress, Chicago, Illinois, 1931-1934. Cloth. Pp. 204. Price, $2. Chicago: Museum of Science and Industry, 1936.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles. By Leading Members of the Medical Profession Throughout the World. Edited by Louis Hamman, M. D., Visiting Physician, Johns Hopkins Hospital, Baltimore, Maryland. Volume II, Forty-Sixth Series, 1936. Cloth. Pp. 327. Philadelphia: J. B. Lippincott Company, 1936.

Scientific Refrigeration in Relation to Nutrition and Health. By Lulu G. Graves, Consultant in Nutrition and Organization of Dietary Departments. Paper. Pp. 16. New York: The Temperature Research Foundation of Kelvinator Corporation, 1936.

BOOK REVIEWS

Passive Vascular Exercises. Louis B. Herman, M. D., University of Cincinnati. Pp. 288, illustrated. Price, $4. J. B. Lippincott Company.

This is an excellent, timely monograph. It imparts excellent new light on a difficult clinical problem. Progress is being made in the treatment of certain vascular conditions. The author has well stated principles and methods. Internists and surgeons will find this monograph to be of great value. W.

Elements of Psychology. By Knight Dunlap, Professor of Psychology, University of California, Los Angeles. Pp. 444. Price, $3. C. V. Mosby Company.

An acceptable presentation of major elements. W.

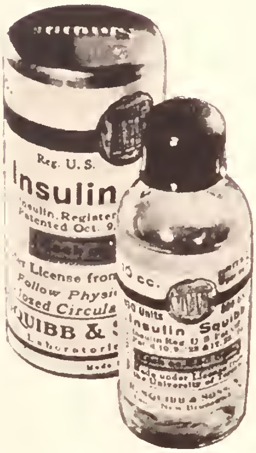
pH



Manufactured under license from the University of Toronto

Highly purified

Purification of Insulin, the separation and elimination of proteinous impurities is dependent upon the precise control of "pH" (hydrogen ion concentration). The continuous automatic recording of pH values permits of far more accurate control than occasional tests. . . . This is just one of the many precautions taken in the manufacture of Insulin Squibb—noted for its uniform potency, purity, stability and marked freedom from proteinous reaction-producing substances. . . . Available in 5-cc. and 10-cc. rubber-capped vials—in usual "strengths."

ONLY THE BEST
is good enough for baby

THERE can be no compromise with quality in baby foods. Infant nourishment must be the best procurable—high in nutrients, easily digestible and appetizing. When you prescribe Heinz Strained Foods, you make *doubly* sure that this need for unusual excellence is fulfilled. Here are the facts:

For more than three generations American housewives have accepted the Heinz "57" seal as a dependable guide to outstanding food quality. Today *your* exacting profession accepts the claims of high quality and nutrient values made for Heinz Strained Foods, permitting the use of the coveted Seal of Acceptance of the American Medical Association's important Committee on Foods.

Specify Heinz Strained Foods *by name* for both infants and invalids. You are *doubly* protected in doing so. Write, also, for the new Heinz Book of Nutritional Charts. We believe you will find it interesting. It's free. Address Dept. CW307, H. J. Heinz Company, Pittsburgh, Pa.

HEINZ STRAINED FOODS

BOOK REVIEWS

(Continued from Page 14)

Patient and the Weather. By William F. Petersen, M. D., University of Chicago. Cloth. Pp. 781. Price, $9. Edward Brothers, Ann Arbor, Michigan.

With many graphs, charts, and illustrations, the author develops his subject of the effect of weather on individuals. Cyclonic circulation, atmospheric pressure, temperature, humidity, sunlight, electricity, meteoropathology, are discussed in detail and their effect upon the human individual. A tremendous amount of material is given and effects are illustrated by many case histories and clinical studies. There are 388 illustrations.

Physicians will find much of interest and assistance in this text. It belongs in every internist's library. W.

Medical Science Exhibits—A Century of Progress. By Eben J. Carey, M. D. Price, $2. Write to P. J. Byrne, 624 South Michigan Avenue, Chicago, Illinois.

Doctor Carey, the director of medical exhibits of the 1931-1934 Chicago Century of Progress, has well set forth, by means of illustrations and descriptive text a permanent record of the work in preparing the exhibits and their final completion. This book should be very useful to those who sponsor similar exhibits in public expositions and in museums. W.

International Clinics. A Quarterly. Vol. II, Forty-Sixth Series. J. B. Lippincott Company.

Fourteen articles on current subjects of helpful value and up to the established standard of these clinical publications. W.

Security Against Sickness. A Study of Health Insurance. By I. S. Falk. Cloth. Pp. 423. Doubleday, Doran & Company, New York.

The author, known as a proponent for health insurance and a persisting agitator of the question, has given a comprehensive and favorable statement of foreign methods. He discusses some American conditions. He concludes with a restatement of his repeated deductions and arguments. Worth reading, but not acceptable for American people or the profession of medicine. W.

TWENTY-FIVE YEARS AGO

(Continued from Text Page 112)

sized the value of decompression and made great improvements in the technique of the operation, that the procedure became well known and quite generally adopted. . . .

From an article on "Functional Insufficiencies of the Myocardium" by H. D'Arcy Power, M.D., San Francisco.

I have not chosen the subject of this paper on account of any new light I can shed upon an old story, nor have I any extensive series of cases to record, but because, in the daily run of general practice, the victims of the condition I am to deal with are numerous and constitute an important element of our clientele. Yet, nevertheless, their symptoms are too often misinterpreted; sometimes, perhaps, unavoidably so. . . .

From an article on "The Treatment of Hemoptysis in Tuberculosis" by Max Rothschild, M. D., San Francisco.

One of the most erratic and most alarming symptoms in tuberculosis of the lungs is hemoptysis—erratic because we see many cases of advanced phthisis which never have had a hemorrhage, or even a trace of blood in their sputum; and we see other cases in which a sudden hemorrhage is the first symptom of the disease." . . .

From an article on "The Hypodermic Use of Hexamethylenamin" by F. F. Gundrum, M. D., Sacramento.

The first work published concerning the excretion of hexamethylenamin, when used on laboratory animals and

clinically, was that of Crowe, in 1908. He was able to show in the laboratory that, following the administration of hexamethylenamin by mouth, the drug was excreted in the bile, pancreatic juice, saliva, milk, and urine of dogs. . . .

From an article on "Rabies in California" by W. A. Sawyer, M.D., Director of State Hygienic Laboratory, Berkeley.

For a year and a half there has been prevalent among dogs in certain parts of California a disease frequently transmitted to other warm-blooded animals, including cattle and horses, and also to man. Rabies, or hydrophobia, is a striking example of those diseases which are perpetuated among certain animals and occasionally are transmitted in one way or another to man. . . .

The Pacific Slope, after a long freedom from the disease, has at last been forced to add rabies to the list of diseases which demand suppression through concerted activity of the defenders of the public health. . . .

In a recent article Black and Powers describe a small outbreak of rabies among the dogs of Los Angeles in 1898. . . .

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 112)

syndicate engaged in illegal operations, into police headquarters this afternoon. . . . According to the police . . . these were seized in raids on four Hollywood medical establishments. . . . " (United Press dispatch, dated Hollywood, June 5, and printed in the Pasadena *Post*, June 1, 1936.)

"Sufficient paraphernalia to run a miniature hospital was seized in a raid conducted yesterday on the Oakland offices of the late Dr. J. B. Folsom in connection with investigation of an alleged coast-wide illegal operation ring. The raid was headed by Assistant District Attorney Frank Coakley of Alameda County. Coakley stated that the offices, located at 3849 Grove Street, represented 'a complete illegal operation layout with sufficient equipment for running an abortion institution of elaborate and unlimited capacity.' . . . The offices assertedly were purchased five months prior to Doctor Folsom's death on July 31, 1935, by Dr. George E. Watts of Los Angeles, alleged part owner of the abortion ring." (San Francisco *Examiner*, June 14, 1936.)

"Dr. George H. Wymann, brought into court Tuesday morning for preliminary arraignment following his arrest last May 13, growing out of his assertedly performing an illegal operation upon the person of Sylvia A. Carr, was ordered held under $10,000 bail. . . . The crime against the physician was brought to light when the patient, who resided at 1009 East Fifty-sixth Street, succumbed following the performance of the illegal operation. . . . Although he enjoyed a comparatively lucrative practice, the playboy doctor persisted in having occasional brushes with authorities over some provisions of legal and ethical practice. Trafficking in drugs and petty theft have proved sufficient for imprisonment for him on separate occasions. . . ." (Los Angeles *Eagle*, May 22, 1936.)

(Continued on Page 20)

The general practitioner now treats . . . . **HAY FEVER** *Successfully*

Hay Fever, it is estimated, affects at least two per cent. of the white population of this country. This means that five of each 250 patients seen by the General Practitioner in the course of a year suffer from attacks of Hay Fever in the early summer or fall. Four out of five of these distressingly afflicted victims can be given decided relief by means of a standardized series of injections.

Such a series of injections is available when Pollen Antigen *Lederle* is employed.

Treatment sets comprise fifteen graduated doses which simplify the administration of appropriate amounts of the specific Pollen Antigen.

WHY CAMP SUPPORTS ARE ACCURATELY FITTED

It is no mere accident, or fortunate circumstance, that you are assured accurate fittings for those of your patients for whom you prescribe Camp supports. Camp Schools for Surgical Fitters are conducted from time to time in a great many cities, both large and small, throughout this country and in Canada and Europe. Classes range in size anywhere from three or four members of a department of one particular store to two hundred fitters from many stores. Class rooms are hotel assembly rooms or Camp branch offices. The larger schools—held in eight principal cities—last a full week.

Six lectures in all are given . . . on the anatomy and physiology concerned with the mammary gland, visceroptosis, hernia, postoperative, pregnancy and orthopedic conditions. A skeleton, charts, stereopticon slides and motion pictures: These are equipment used by the Camp medical director. A handbook carefully compiled is the textbook for the course, a textbook which the surgical fitter retains for reference.

After this technical background, there follows a practical exposition of the principles involved in the design of Camp supports. Actual patients obtained from clinics of leading hospitals serve as models and are fitted before the class.

Table talks and intimate discussions relating to everyday problems encountered by fitters in their store work are carried on following the classwork. Experienced Camp nurses and instructors are in charge, and they attempt to give each student-fitter personal attention. Fitters are instructed not to diagnose or treat disease, and do not fit garments except in coöperation with physicians.

S. H. Camp & Company has conducted these schools for surgical fitters for eight years. Several thousand fitters have thus learned why supports are prescribed and exactly how to adjust Camp garments typed to body build . . . all without cost to the stores or the fitters . . . and to the end that your patients may be accurately fitted. This is an important part of the Camp Professional Support Service.

Definite Potency Means Definite Response

DIGIFOLINE "CIBA"

In the employment of digitalis, the first rule is to know the strength of the preparation in terms of efficient response. You can depend on the uniformity of Digifoline, "Ciba," and accurately judge response according to dose.

DIGIFOLINE, "Ciba"—containing the essential cardio-active glucosides of digitalis leaf, and free from inert or undesirable substances—is assayed by the Hatcher and Brody Method to assure uniformity.

Where oral administration is impracticable or rapidity of action is essential, the ampule form of Digifoline, "Ciba" is suitable for intramuscular or intravenous injection.

Each tablet, each ampule, each cc. of liquid equals one "cat unit"—or 1½ grains of high grade digitalis leaf.

IMPORTANT—Your patient now receives 50 Digifoline, "Ciba" Tablets for the price formerly charged for 25.

TABLETS • LIQUID • AMPULES

BOARD OF MEDICAL EXAMINERS

(Continued from Page 18)

Doctor Wymann's license was revoked by the Board of Medical Examiners October 23, 1924, and on October 17, 1927, restored, he being placed on probation for a period of five years.

"Oakland police and federal narcotic agents joined yesterday in a surprise raid on the West Oakland office of Dr. John Charles Coleman, jailing him. Coleman, thirty, was charged with the illegal sale and possession of drugs and with having written fictitious prescriptions calling for narcotics. . . ." (San Francisco *Chronicle*, May 30, 1936.)

"Another resolution that created a stir before it was adopted by the legislature at the recent special session, was by Assemblyman Hunt, calling for appointment of a committee and an appropriation of $300 to investigate violations of the Medical Practice Act, particularly the matter of illegal operations. Hunt charged, in arguing for his resolution, that there is a syndicate operating a chain of places where such operations are performed and that in a downtown Los Angeles office building an entire floor is devoted to a 'hospital' for such purposes." (Los Angeles *Times*, May 27, 1936.)

"Trial of Dr. J. Douglas Thompson, licensed chiropractor, who will face the court a second time on charges of false advertising, was set today for June 2, by Police Judge Joseph A. Kennedy after he overruled a demurrer to the amended complaint filed by Joseph Brown, Doctor Thompson's attorney. Brown contended certain sentences were deleted from the amended complaint, which narrowed the issue down and asked that they be reinstated.

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M.D., 490 Post Street, San Francisco, California.

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

BOARD OF MEDICAL EXAMINERS

(Continued from Page 20)

A jury disagreed at the first trial of Doctor Thompson, who specifically was alleged to have advertised a product in violation of the medical laws." (Oakland *Tribune,* May 12, 1936.)

"Dr. J. Walter Clark, South Gate and Huntington Park chiropractor, today was free on three years' probation in connection with the burglarizing of the Los Angeles Drug Company of $30,000 worth of drug accessories in five months. . . ." (Huntington Park *Signal,* May 9, 1936.)

"Lloyd Garrison, thirty, chiropractor, 2971 California Street, with offices at 858 Sutter Street, yesterday heard himself charged in Municipal Court with performing an illegal operation. Bernice Rousse, twenty-five, 250 Taylor Street, waitress, now being treated in San Francisco Hospital, was the victim, the court was told." (San Francisco *Chronicle,* May 26, 1936.)

"Dr. Karl F. Meyer, director of the Hooper Foundation for Medical Research in the University of California, was today awarded the degree of Doctor of Medicine, Honorary, by the College of Medical Evangelists of Los Angeles. The award was made in recognition of his work in the field of public health." (San Francisco *News,* June 2, 1936.)

Federal Food and Drugs Act Report.—Fresh, canned and frozen fish and shellfish presenting a variety of violations of the Federal Food and Drugs Act were seized in April, says a report by the Food and Drug Administration. Decomposition, the commonest cause of adulteration, again leads the list. Shipments seized on that account included 41,100 cases of canned salmon, 1,016 cases of canned tuna, 10,150 pounds of frozen shrimp, and 275 cases of canned shrimp. The canned shrimp was also misbranded because the cans bore a label approved for use only on inspected shrimp, and the goods seized were packed in a plant not under inspection. Tullibees, a strain of whitefish seized in great quantities in recent years, are still found in interstate commerce infested with threadlike encysted worms; 48,100 pounds were seized in April.

Six shipments of refrigerated crabmeat from Florida, carrying certain bacteria associated with filth, were seized at norther destinations, and 2,700 cans of oysters, adulterated with excessive and dangerous quantities of broken oyster shell, were confiscated. The pieces of shell varied in size from tiny slivers to plates an inch square. Raw

oysters in pint cans (300 cans) also were picked up on a showing that they were short in volume.

Dairy Products, Other Foods Seized.—Dairy products seized during the month were the following: 145 pounds of butter short in weight and containing less than the legal requirement of butterfat; 400 pounds of dirty "packing stock" butter; 100 jars of a limburger cheese spread containing particles of insects and animal hairs; 10,567 pounds of miscellaneous cheeses damaged in the March floods; and 390 packages of a purported "Old English" cheese claiming to owe its sharp flavor to its age and curing process, when in fact a liberal admixture of red pepper was the element that left the advertised "tingle on the tongue." . . .

Late seizures, winding up the campaign against isopropyl alcohol mixtures masquerading as the conventional grain-alcohol rubs, involved 420 bottles of the misbranded solution. One pharmaceutical only was seized in April—a shipment of pituitary solution found on test to be below the legal standard of strength.

Patent Medicines.—Patent medicines are conspicuously present in the report. The products seized, their compositions, and the curative claims alleged to be false and fraudulent, are as follows:

"Anti-Itch," a petrolatum ointment containing zinc oxid, glycerol, wintergreen and carbolic acid (10.63 per cent), for itch, scabies, eczema and other skin irritations (the product was also held to be misbranded under the Federal Caustic Poison Act since it had no label statement of the common name of the poison it contained, no "Poison" warning, and no antidote in case of accidental injury).

"Booth's Hyomei," a solution of eucalyptol, menthol and creosote in alcohol and water, for catarrh, hay fever, catarrhal coughs, croup, bronchitis, catarrhal laryngitis, lung affections and difficult breathing (the product was further misbranded in declaring an alcohol content of 12 per cent when it contained only 9 per cent, and in representing its vapors as antiseptic).

"Bralot Rheumatic Tablets," containing amidopyrin, sodium salicylate, and coated with chocolate, for rheumatism, gout, neuralgia, neuritis and sciatica.

"Diaplex," consisting of the dried leaves and stems of the salt bush, for diabetes.

"Four Leaf Clovers," pink tablets containing boric acid, borax and starch, falsely represented as antiseptic, and for various ailments of women.

"G. S. Alterative Tonic," a solution of plant drugs and potassium iodid in alcohol and water, for pellagra, rheumatism, liver and kidney ailments, and as a tonic.

"H. P. Antiseptic and Healing Balm," a lead oleate ointment not antiseptic as represented, and claimed safe despite its lead content, for piles, putrid sores, proud flesh, gangrene, lead poisoning, gunshot wounds, all infections, eczema, sores, tick bites, barber's itch, felons, boils, carbuncles, erysipelas, blood poisoning, x-ray burns, ringworm, impetigo, septicemia, pyemia, nasal infections, sinus trouble, hay fever, ulcers and mercury sores.

"Hi-Test Catarrhal Jelly," a deteriorated salvage drug containing petrolatum, menthol and eucalyptol, for catarrh and hay fever; "Kopp's," a syrup containing the narcotic morphin sulphate, represented as safe for children.

"Lacta Kaolin Alpha," consisting of lactose, kaolin (clay), agar and cocoa, represented as a food, although composed chiefly of non-food ingredients; "Lacta-Kaolin Laxative," of the same composition as the preceding product, with the addition of the coal-tar laxative phenolphthalein, the label, however, representing the difference between the two as one of agar and cocoa content, without reference to the presence of the laxative drug, for dysentery, cholera, gastro-enteric disorders, halitosis, intestinal and colon disorders, toxemia, auto-intoxication, high blood pressure, and bilious conditions.

"Mentos," a water solution of sulphur, borax, ammonia, and perfume, represented as antiseptic but found on test incapable of killing pathogenic organisms, for dandruff, ringworm, falling hair, scaling scalp, psoriasis, eczema,

skin diseases, pimples, warts, and to prevent baldness and restore hair.

"Mother Beach Stomach Tablets," made of sodium bicarbonate, bismuth subnitrate and magnesium oxid, for stomach ulcers, indigestion, dyspepsia, headaches, and lack of appetite.

"My-Kel Tooth Powder," sodium perborate and talc, flavored with wintergreen, for keeping the gums firm, building up the tooth enamel, for pyorrhea, and to maintain freedom from mouth infections.

"Quality Sealed Sore Throat Remedy," another deteriorated salvage drug, a solution of potassium chlorate, tannic and carbolic acid in glycerin and water, short of the declared volume, for sore throat.

"Tricasco," a solution of plant extracts, licorice, a laxative and sugar, for forty ailments, including consumption, pneumonia, rheumatism, palpitation of the heart, gout, gall-stones, and stomach ulcers.

"Ward's Vitamized Tonic Tablets," containing iron, iodin, calcium, a fish-liver oil and berberin, making claims of vitamin A and D potency that were found on test to be unsupportable.

Spotted Fever in East Again, So Beware of the Dog Ticks.—Three recent cases of Rocky Mountain spotted fever near Washington, D. C., emphasize the need for vigilance against the wood ticks, or dog ticks, that spread this disease, warns Dr. F. C. Bishopp of the United States Department of Agriculture. Fortunately, Doctor Bishop says, only a small proportion of these common ticks are infected. The disease, however, is widespread and has a high mortality. In the East infected ticks are known to occur in Maryland, Virginia, Delaware and North Carolina, and cases of spotted fever have been reported from nearly all states in the eastern part of the country except in New England, Ohio, Michigan, Wisconsin, and Mississippi. A large percentage of the cases reported in the East have been in Maryland and Virginia in the vicinity of Washington, D. C., and in North Carolina. In the far West, spotted fever is carried by a different species of tick.

Despite the cold winter, ticks are unusually abundant in the East this year. As many as a hundred have been picked off a dog at the end of a day in the woods. Although adult ticks prefer the blood of dogs, they may attach themselves to horses, cattle, and larger wild animals, as well as to man. The young ticks—"seed ticks" or "nymphs"—relish the blood of meadow and pine mice and other small wild animals. In fact, ticks disappear when there are none of these little animals on which they can feed in their early stages. Clearing out the underbrush that protects both mice and ticks, therefore, cuts down the number of ticks.

Ticks are most numerous in the early summer. Usually they practically disappear by the first of August, making the late summer safer for camping trips and hikes.

Doctor Bishopp emphasizes the importance of confining dogs in yards throughout the tick season and of examining them frequently. Every tick, he says, should be pulled off the dog with forceps and dropped into a can of kerosene. Ticks that have fed on a dog for a few hours are immediately dangerous, but they are not likely to detach until fully fed, and the engorged females will not reattach. As the disease can be contracted from crushed ticks, through cuts or scratches, it is a safety measure to wash the hands thoroughly after touching ticks. Derris powder may be scattered lightly over heavily infested dogs. This kills any ticks on the dog and tends to repel others.

If it is necessary to go into tick-infested places it is advisable to wear high-top shoes over army-type trousers and systematically to examine the body and head at least twice a day. One of the favorite places of attachment is in the hair at the base of the head. Ticks are not likely to transmit the disease unless they remain attached for at least six hours.

Ticks are very hardy, Doctor Bishopp says. They can live from year to year with no food. Adult ticks put in

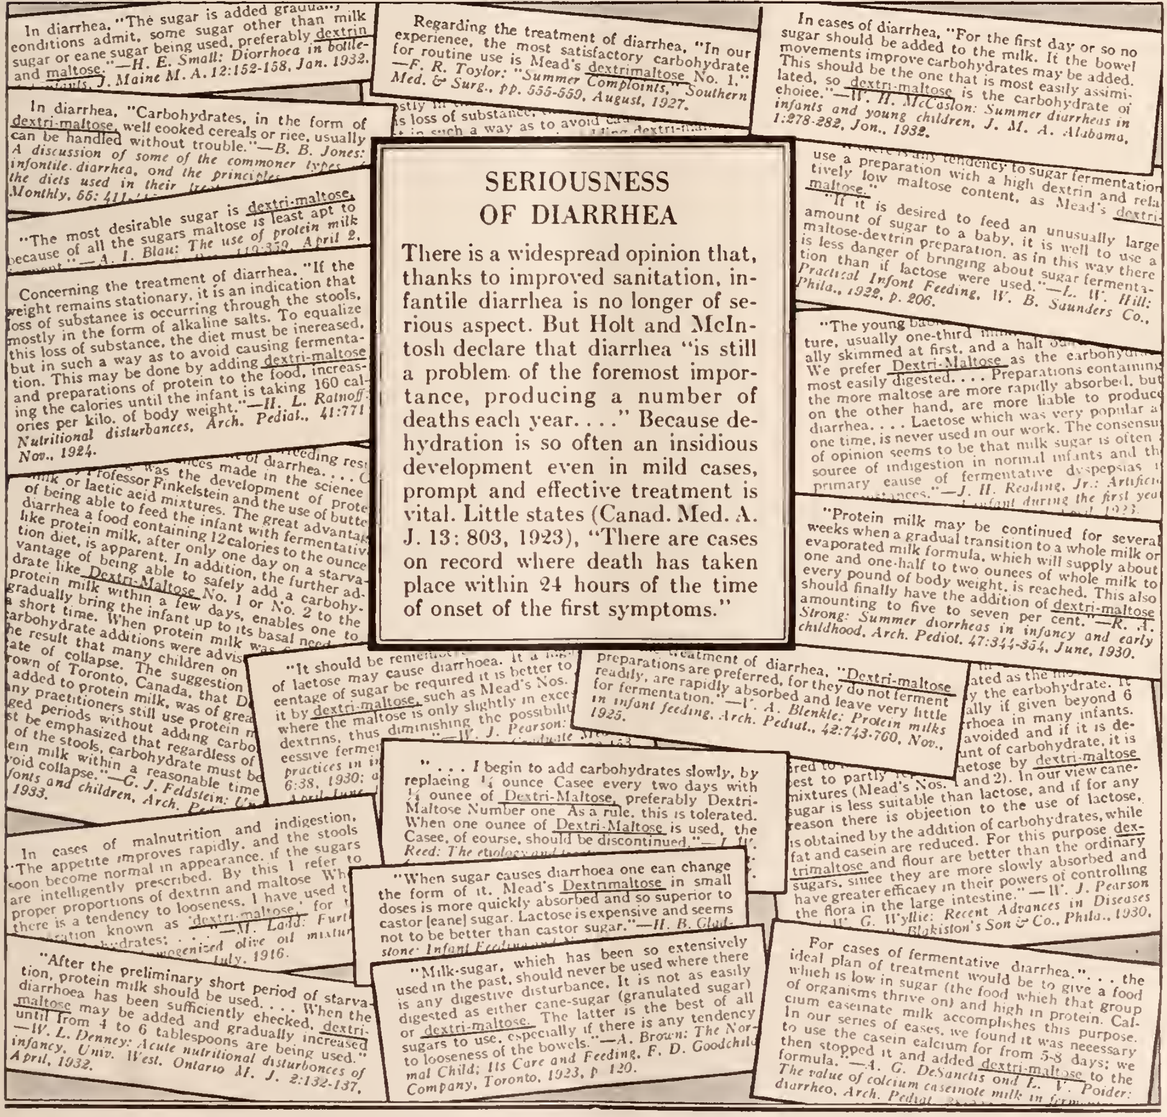
(Continued on Page 26)

DIARRHEA

"the commonest ailment of infants in the summer months"

(HOLT AND McINTOSH: HOLT'S DISEASES OF INFANCY AND CHILDHOOD, 1933)

One of the outstanding features of DEXTRI-MALTOSE is that it is almost unanimously preferred as the carbohydrate in the management of infantile diarrhea.



In diarrhea, "The sugar is added gradua conditions admit, some sugar other than milk sugar or cane sugar being used, preferably dextrin and maltose."—*H. E. Small: Diarrhoea in bottle- J. Maine M. A. 12:152-158, Jan. 1932.*

Regarding the treatment of diarrhea, "In our experience, the most satisfactory carbohydrate for routine use is Mead's dextrimaltose No. 1."—*F. R. Taylor: "Summer Complaints," Southern Med. & Surg., pp. 555-559, August, 1927.*

In cases of diarrhea, "For the first day or so no sugar should be added to the milk. If the bowel movements improve carbohydrates may be added. This should be the one that is most easily assimilated, so dextri-maltose is the carbohydrate of choice."—*W. H. McCaslon: Summer diarrheas in infants and young children, J. M. A. Alabama, 1:278-282, Jan., 1932.*

In diarrhea, "Carbohydrates, in the form of dextri-maltose, well cooked cereals or rice, usually can be handled without trouble."—*B. B. Jones: A discussion of some of the commoner types infantile diarrhea, and the principles the diets used in their Monthly, 66: 411,*

"The most desirable sugar is dextri-maltose, because of all the sugars maltose is least apt to"—*A. I. Blau: The use of protein milk 119:359, April 2,*

use a preparation with a high dextrin and relatively low maltose content, as Mead's dextri-maltose."

"If it is desired to feed an unusually large amount of sugar to a baby, it is well to use a maltose-dextrin preparation, as in this way there is less danger of bringing about sugar fermentation than if lactose were used."—*L. W. Hill: Practical Infant Feeding, W. B. Saunders Co., Phila., 1922, p. 206.*

Concerning the treatment of diarrhea. "If the weight remains stationary, it is an indication that loss of substance is occurring through the stools, mostly in the form of alkaline salts. To equalize this loss of substance, the diet must be increased, but in such a way as to avoid causing fermentation. This may be done by adding dextri-maltose and preparations of protein to the food, increasing the calories until the infant is taking 160 calories per kilo. of body weight."—*H. L. Ratnoff: Nutritional disturbances, Arch. Pediat., 41:771 Nov., 1924.*

"The young ture, usually one-third ally skimmed at first, and a half We prefer Dextri-Maltose as the carbohydrate most easily digested. . . . Preparations containing the more maltose are more rapidly absorbed, but on the other hand, are more liable to produce diarrhea. . . . Lactose which was very popular at one time, is never used in our work. The consensus of opinion seems to be that milk sugar is often source of indigestion in normal infants and th primary cause of fermentative dyspepsias"—*J. H. Reading, Jr.: Artifici infant during the first yea*

feeding res ces made in the science of diarrhea. . . . was the development of prote Professor Finkelstein and the use of butte ilk or lactic acid mixtures. The great advantage of being able to feed the infant with fermentative diarrhea a food like protein milk, containing 12 calories to the ounce, after only one day on a starvation diet, is apparent. In addition, the further advantage of being able to safely add a carbohydrate like Dextri-Maltose No. 1 or No. 2 to the protein milk within a few days, enables one to gradually bring the infant up to its basal need a short time. When protein milk was arbohydrate additions were advis he result that many children on ate of collapse. The suggestion own of Toronto, Canada, that D added to protein milk, was of grea ny practitioners still use protein m ged periods without adding carbo st be emphasized that regardless of of the stools, carbohydrate must be ein milk within a reasonable time oid collapse."—*G. J. Feldstein: Un fants and children, Arch. Pe 1933.*

"Protein milk may be continued for several weeks when a gradual transition to a whole milk or evaporated milk formula, which will supply about one and one-half to two ounces of whole milk to every pound of body weight, is reached. This also should finally have the addition of dextri-maltose amounting to five to seven per cent."—*R. A. Strong: Summer diarrheas in infancy and early childhood, Arch. Pediat. 47:344-354, June, 1930.*

"It should be of lactose may cause diarrhoea. It a centage of sugar be required it is better to it by dextri-maltose, such as Mead's Nos. where the maltose is only slightly in exce dextrins, thus diminishing the possibilit cessive fermen"—*W. J. Pearson: practices in in 6:38, 1930;*

treatment of diarrhea, "Dextri-maltose preparations are preferred, for they do not ferment readily, are rapidly absorbed and leave very little for fermentation."—*V. A. Blenkle: Protein milks in infant feeding, Arch. Pediat., 42:743-760, Nov., 1925.*

ated as the y the carbohydrate. It ally if given beyond 6 rhoea in many infants. avoided and if it is de unt of carbohydrate, it is actose by dextri-maltose red to est to partly and 2). In our view cane- mixtures (Mead's Nos. sugar is less suitable than lactose, and if for any reason there is objection to the use of lactose, is obtained by the addition of carbohydrates, while fat and casein are reduced. For this purpose dextrimaltose and flour are better than the ordinary sugars, since they are more slowly absorbed and have greater efficacy in their powers of controlling the flora in the large intestine."—*W. J. Pearson W. G. Wyllie: Recent Advances in Diseases Blakiston's Son & Co., Phila., 1930.*

". . . I begin to add carbohydrates slowly, by replacing ¼ ounce Casec every two days with ¼ ounce of Dextri-Maltose, preferably Dextri-Maltose Number one As a rule, this is tolerated. When one ounce of Dextri-Maltose is used, the Casec, of course, should be discontinued."—*J. W. Reed: The etiology*

In cases of malnutrition and indigestion, "The appetite improves rapidly, and the stools soon become normal in appearance, if the sugars are intelligently prescribed. By this I refer to proper proportions of dextrin and maltose Wh there is a tendency to looseness. I have used t known as 'dextri-maltose,' for drates; . . ."—*M. Ladd: Furt olive oil mixtur July, 1916.*

"When sugar causes diarrhoea one can change the form of it. Mead's Dextrimaltose in small doses is more quickly absorbed and so superior to castor [cane] sugar. Lactose is expensive and seems not to be better than castor sugar."—*H. B. Gladstone: Infant Feeding*

"After the preliminary short period of starvation, protein milk should be used. . . . When the diarrhoea has been sufficiently checked, dextri-maltose may be added and gradually increased until from 4 to 6 tablespoons are being used."—*W. L. Denney: Acute nutritional disturbances of infancy, Univ. West. Ontario M. J. 2:132-137, April, 1932.*

"Milk-sugar, which has been so extensively used in the past, should never be used where there is any digestive disturbance. It is not as easily digested as either cane-sugar (granulated sugar) or dextri-maltose. The latter is the best of all sugars to use, especially if there is any tendency to looseness of the bowels."—*A. Brown: The Normal Child; Its Care and Feeding, F. D. Goodchild Company, Toronto, 1923, p 120.*

For cases of fermentative diarrhea, ". . . the ideal plan of treatment would be to give a food which is low in sugar (the food which that group of organisms thrive on) and high in protein. Calcium caseinate milk accomplishes this purpose. In our series of cases, we found it was necessary to use the casein calcium for from 5-8 days; we then stopped it and added dextri-maltose to the formula."—*A. G. DeSanctis and L. V. Paider: The value of calcium caseinate milk in ferm diarrhea, Arch. Pediat.*

SERIOUSNESS OF DIARRHEA

There is a widespread opinion that, thanks to improved sanitation, infantile diarrhea is no longer of serious aspect. But Holt and McIntosh declare that diarrhea "is still a problem of the foremost importance, producing a number of deaths each year. . . ." Because dehydration is so often an insidious development even in mild cases, prompt and effective treatment is vital. Little states (Canad. Med. A. J. 13: 803, 1923), "There are cases on record where death has taken place within 24 hours of the time of onset of the first symptoms."

Just as DEXTRI-MALTOSE is a *carbohydrate* modifier of choice, so is CASEC (calcium caseinate) an accepted *protein* modifier. Casec is of special value for (1) colic and loose green stools in breast-fed infants, (2) fermentative diarrhea in bottle-fed infants, (3) prematures, (4) marasmus, (5) celiac disease.

vials without food on April 10, 1933, for observation, are still alive and vigorous. Hence it cannot be assumed that an area is tick-free, even if all the animals on which they might live have been driven out or destroyed in one season.

Besides being carriers of spotted fever, ticks sometimes cause a form of paralysis. The effect of their bites often persists for months.

Nebraska Is Fortieth State to Eradicate Bovine Tuberculosis.—Nebraska on June 1 was officially designated by the United States Department of Agriculture as a modified accredited area, signifying that the state is practically free from bovine tuberculosis. Nebraska is the fortieth state to attain such recognition.

As Nebraska is a state with a large number of cattle, it was necessary to conduct a great many tuberculin tests. The greater part of the testing was done during the last two years. Livestock owners in nearly all sections of the state coöperated.

The accreditation of Nebraska is especially significant in view of the large number of feeder cattle that are shipped from the state and may now be shipped without a special tuberculin test. It will be necessary now only to retest the various counties at regular intervals. Retesting is a precaution to keep the disease from getting another foothold, officials explain. Although retesting is not so difficult as the first tests, it is essential and causes little inconvenience to herd owners.

Of the eight remaining states not in the modified accredited area, one, South Dakota, is in the Middle West, one, California, is on the Pacific Coast, and six, New York, New Jersey, Pennsylvania, Maryland, Vermont, and Rhode Island, are in the northeastern group of states. It is expected that some of this territory will be accredited within the next few months.

"Quality" Milk.—Dr. M. J. Rosenau of Harvard University said recently, in discussing the subject of quality in milk: "A man of quality is at once certified with superior attributes. It is the same with milk. There are grades in the ranks of quality. Certified milk ranks with royalty, Grade A stands in the fine fellowship of the legion of honor, and pasteurized milk is captain of the league of peace and security." Thus did the eminent physician and sanitarian suggest the importance of quality in milk and at the same time subtly indicate the relationship of different grades of milk to each other and to their users.

What Is "Quality" Milk?—Continuing his discussion, Doctor Rosenau asks himself the question, "What is 'quality' milk?" and answers it by saying: "It is clean milk of uniformly low bacterial content, free from dirt and pathogenic organisms. It is produced from healthy cows, free from tuberculosis, Bangs' disease, mastitis, and all other maladies, and is handled by healthy employees, using sanitary methods and clean and sterile equipment and utensils. Finally, such a safe milk must also be relatively high in nutritive values, with an ample content of butterfat and total solids, and an abundance of normal vitamins, the content of some of which in milk is definitely influenced by the ration fed to the cow."

Today public health authorities and the dairy industry agree that general market milk distributed in cities should be pasteurized. According to estimates of the Office of Milk Investigation of the United States Public Health Service, nearly 90 per cent of all milk now sold in cities of 10,000 or more population is pasteurized. The story of "peace and security" thus established is told in the record of decline and practical elimination of milk-borne disease in this country.

What Is Certified Milk?—Certified milk has, as a rule, been exempt from pasteurization because of the unusual

For Acidity and Allied Conditions, we suggest

ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

precautions which must be observed in its production and handling, and the careful medical, veterinary, sanitary, and laboratory supervision applied to it under the direction of a medical milk commission appointed by the local medical society. Milk may be labeled "certified" and sold as such when it meets the rigid requirements imposed by this commission.

The local medical milk commissions in the United States, now approximately eighty in number, are working toward unification in policies and standards under the American Association of Medical Milk Commissions. Each local commission employs a physician, a veterinarian, a sanitary inspector, and a laboratory technician, who are directly responsible for maintaining standards of quality for certified milk within a specified territory.

The American Medical Association has recently pointed out editorially the importance of certified milk in the entire line of progress of the dairy industry. "The value

of certified milk has been great, even to those who have never used certified milk. Through the experience developed by methods of certification, the general level of sanitation in milk production has been raised. Producers of certified milk have furnished invaluable leadership in the dairy industry. At the same time the necessarily high cost of certified milk, which rendered it inaccessible to most consumers, made necessary the availability of a supply of milk that could be relied on for safety and yet could be supplied at much less expense."

Certified Milk—Pasteurized.—Although the long record of certified milk, as a safe product, is practically unchallenged, many sanitarians have urged repeatedly that it be pasteurized, merely as an added safeguard. Recently definite progress has been made in this respect. Following the annual meeting of the American Association of Medical Milk Commissions in June, 1935, the official methods and standards for certified milk were amended to permit producers of certified milk to pasteurize their product. Milk of certified quality may now be sold either raw or pasteurized in most localities, if properly labeled to distinguish it between the two kinds. The cap of the pasteurized milk must bear the legend "Certified Milk—Pasteurized."

The American Medical Association hailed this announcement of permissive pasteurization of certified milk with the statement: "Physicians desiring the highest quality of pasteurized milk for their patients will now be able to prescribe pasteurized certified milk; producers of certified milk will be able to offer their customers a pasteurized product; public health authorities will be aided in their program of universal pasteurization, and milk consumers will have a wider choice among desirable milk supplies." The American Public Health Association voiced its approval of the measure as follows: ". . . the action taken in favor of permissive pasteurization was a landmark in the development of certified milk, an episode which is as significant to dairy science and to public health as was the institution of certified milk itself in 1893."

Nupercainal

"Ciba"

Nupercainal is issued in tubes (with removable paper labels) of one ounce and in tins of one pound.

the LOCAL ANESTHETIC OINTMENT of PROLONGED ACTION

Makes the patient comfortable under trying circumstances

North, East, South, West, physicians find that Nupercainal, "Ciba", by emollient and penetrating local anesthetic actions, promptly takes the pain and sting out of sunburn and other superficial burns. It is antipruritic and an aid in healing. Relief is prolonged.

Other Indications:—Itching and distress of hemorrhoids, pruritus ani et vulvae, various dermatoses, decubitus, cracked nipples, anal fissures, etc.

Try Nupercainal clinically. Send for free trial sizes and literature.

CIBA COMPANY, INC., NEW YORK, N. Y.

Those users of certified milk who prefer the added safety of pasteurization will welcome the information that the food value of pasteurized milk is virtually the same as the milk before it is pasteurized. Experiments show that the growth promoting and calcifying properties of milk, and the vitamins A, G, and D are unaffected by the process. There is some destruction of vitamins B and C in pasteurization, but these vitamins are supplied abundantly in certain other common foods and, therefore, the loss in milk is not regarded as important.

The Flavor of "Quality" Milk.—Delicious flavor is always associated with "quality" milk. Regardless of the particular grade or classification into which this milk may fall, the fresh, wholesome flavor of all "quality" milk adds infinitely to the consumer's enjoyment and appreciation of it. Each meticulous step in the care and feeding of the cow and in the handling of the milk itself contributes to the protection of that delicate, elusive flavor characteristic only of "quality" milk.

Summary.—1. Certified milk is so designated by medical milk commissions which establish optimal standards for care of the cows, for handling the milk, and for the bacterial content of the milk itself.

2. The American Association of Medical Milk Commissions has recently agreed to permit producers of certified milk to pasteurize their milk under certain specified conditions.

3. Pasteurization does not affect unfavorably those nutritive constituents present most abundantly in milk and which consumers must depend upon receiving chiefly from milk.

Dental Practice Acts: Dentistry Not Divisible into Professional and Business Departments.—The dental practice act of Wisconsin authorizes the state board of dental examiners on its own motion to make investigations and conduct hearings "in regard to the action of any licensed dentist and dental hygienist or any person who it has reason to believe is acting or has acted in such capac-

ity within the state." Acting under this authority, the board served notices on Painless Parrmer, Inc., and A. J. Rust, a stockholder of that corporation, ordering them to appear before the board on a certain day "to give evidence." Rust and the corporation sought to restrain the board from holding the hearing, and from an adverse decision of the trial court they appealed to the Supreme Court of Wisconsin.

The constitutionality of reasonable regulations over the dental profession has been upheld, said the court. The creation of the state board of dental examiners and the conferring on them of the power of investigation and of holding hearings in certain matters specified in the statute are well within the constitutional requirements of an effective law. The legislature may enact legislation designed to accomplish the regulation of matters properly within the legislative field and may authorize an administrative commission, within valid limits, to provide rules and regulations for the administration and enforcement of the law within its expressed general purpose. This includes the right to conduct investigations and hold hearings pertinent to such purpose. The dental practice act in authorizing the board to hold hearings and to subpena witnesses violated no constitutional rights of the plaintiffs.

The plaintiffs contended, however, that the board was without jurisdiction to hold the proposed hearing because neither of them was licensed to practice dentistry. The fact that the plaintiffs do not actually engage in the performance of dental operations is not controlling, said the court. The law contemplates regulation of the profession to such an extent as to protect the public not only against the unprofessional conduct of licensed dentists but also against other persons who, by management or some other intimate relation, are in charge of those who are practicing dentistry under a single management. The method of operating a dental corporation, the securing of patients desiring dental treatment by licensed dentists, is a proper subject to regulation under a system which recognizes the practice as a profession. The contract for the dental work is consummated between the plaintiffs and the patient, the advertising by the corporation is also the act of the plaintiffs and in this manner they are holding themselves out as licensed dentists. In the case of *Painless Parker* v. *Board,* 216 Calif. 285, 14 P. (2d) 67, the court, in answer to the contention that there is a distinction between the practice of dentistry and the purely business side of the practice, stated:

> The law does not assume to divide the practice of dentistry into that kind of departments. Either one may extend into the domain of the other in respects that would make such a division impractical if not impossible. The subject is treated as a whole. If the contention of appellant be sound, then the proprietor of the business may be guilty of gross misconduct in its management and violate all standards which a licensed dentist would be required to respect and stand immune from any regulatory supervision whatsoever. His employee, the licensed dentist, would also be immune from discipline upon the ground that he was but a mere employee and was not responsible for his employer's misconduct, whether the employer be a corporation or a natural person. On grounds of public policy such a condition could not be countenanced. . . . .
>
> No one would dispute the right of any person to own a dental office equipment. The question most appropriate here is whether the thing owned is used for a given purpose by a person lawfully entitled to so use it. Ownership is not the absolute test of the right of use.

The notices that were sent to the plaintiffs, said the court, were lacking in fullness of detail and contained no careful statement of the charges, if any, which the board had under consideration. This fact, however, constitutes no warrant for the granting of injunctional relief. If and when the plaintiffs are accused of violating the provisions of the dental practice act, they will be afforded the opportunity of demanding a proper complaint in that proceeding.

The Supreme Court therefore affirmed the order of the trial court, which, in effect, dismissed the action instituted by the plaintiffs." (*Rust* v. *State Board of Examiners of Wisconsin* (Wis.), 256 N. W. 919.)—*Medicolegal Abstract, Journal of the American Medical Association.*

IF VITAMINS COULD BE COUNTED LIKE EGGS IN A BASKET . . .

Then almost anyone could purchase a vitamin product wisely. But the plain fact is that even you, the physician, cannot determine a vitamin product's potency by any simple test. So, prime factors to consider are the manufacturer's *responsibility* and *ability* in safeguarding quality.

It is unfortunate but true that products supplying Vitamins A and D are sold which do not meet their label claims. Therefore, to make certain that your patients get a product of dependable Vitamin A and D potency, it is well to write all your prescriptions for Haliver Oil with Viosterol and to specify *Abbott*. This product's excellence is guaranteed not only in words but by manufacturing methods and rigid assays.

From the time the fish are caught and the livers immediately removed and iced, to final bio-assaying in an entirely modern, air-conditioned laboratory, Abbott completely controls each step in the manufacture of this specialty. No unknown source of material, no outside processing beclouds certainty of quality! And even when the product is released to the druggist, Abbott's work is not done. For from manufactured lots, samples are kept and bio-assayed at regular intervals to verify stability of that awaiting sale in pharmacies.

Patients who need additional Vitamins A and D for any reason, shut-ins, convalescents, expectant and lactating mothers appreciate the physician's thoughtfulness in prescribing this easy-to-take, entirely tasteless product. With warm weather months coming, it is also important that while each tiny, soft 3-minim capsule contains the same number of Vitamins A and D as four teaspoonfuls of cod liver oil, the caloric content is only one-eightieth as great.

Abbott's Haliver Oil with Viosterol is available in prescription pharmacies everywhere in 25, 100 and 250 3-minim capsules; and in 5-cc. and 50-cc. vials with special droppers.

Abbott's Haliver Oil

With Viosterol

ABBOTT LABORATORIES A-7-36
North Chicago, Illinois

Please send sample of Haliver Oil with Viosterol.

ELI LILLY AND COMPANY

FOUNDED 1876

Makers of Medicinal Products

SOLUTIONS OF LIVER EXTRACT

for the Treatment of Pernicious Anemia

Prepared according to improved methods which minimize the loss of the antianemic materials originally contained in whole liver. Clinical application abundantly demonstrates the ability of these solutions to produce maximal reticulocyte response when administered at reasonable and convenient intervals.

Solution Liver Extract Concentrated, Lilly, is supplied in 10-cc. rubber-stoppered ampoules and in packages of four 3-cc. rubber-stoppered ampoules.

Solution Liver Extract, Lilly, is supplied in 10-cc. rubber-stoppered ampoules.

Subscription prices, $5 ($6 for foreign countries); single copies, 50 cents.

Volumes begin with the first of January and the first of July. Subscriptions may commence at any time.

Change of Address.—Request for change of address should give both the old and the new address. No change in any address on the mailing list will be made until such change is requested by county secretaries or by the member concerned.

Responsibility for Statements and Conclusions in Original Articles.—Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. It is aimed to permit authors to have as wide latitude as the general policy of the journal and the demands on its space may permit. The right to reduce or reject any article is always reserved.

Contributions—Exclusive Publication.—Articles are accepted for publication on condition that they are contributed solely to this journal.

Contributions—Length of Articles: Extra Costs.—Original articles should not exceed three and one-half pages in length. Authors who wish articles of greater length printed must pay extra costs involved. Illustrations in excess of amount allowed by the Council are also extra.

Leaflet Regarding Rules of Publication.—CALIFORNIA AND WESTERN MEDICINE has prepared a leaflet explaining its rules regarding publication. This leaflet gives suggestions on the preparation of manuscripts and of illustrations. It is suggested that contributors to this Journal write to its office requesting a copy of this leaflet.

CORONADO ANNUAL SESSION OF 1936

Proceedings of the San Diego-Coronado Annual Session.—San Diego newspaper comments, reprinted in last month's issue of CALIFORNIA AND WESTERN MEDICINE (pp. 537-540), afforded some views of the laity on happenings at this year's session of the California State Association at Coronado. The current journal presents, on pages 69 and 93, more detailed minutes of the House of Delegates, the Council, and the first general session.

Members of the Association interested in the policies adopted or emphasized at Coronado should read the official record of the transactions, to better acquaint themselves with what was done. This suggestion is made particularly to officers of component county societies, since they are the officials who may be called upon to interpret, from the standpoint of the new regulations, matters of conduct or ethics.

The Coronado-San Diego session measured up in excellent fashion to the successful and enjoyable meetings held in previous years at the Hotel del Coronado; and, as in former days, those who attended were recipients of the gracious hospitality from the San Diego County Medical Society, to whose members appreciation and thanks are expressed for the many courtesies extended.

* * *

California Medical Association's Change of Attitude on Health Insurance.—If one outstanding feature of the attitude of the Coronado House of Delegates, on matters of major policy, deserves mentioning, it would be this: that evidently a somewhat radical change of front concerning health insurance is quite apparent in the California Medical Association, as compared with points of view to which strenuous expression was given at Riverside in 1934, at the memorable special session in Los Angeles in 1935, and at the later regular session of the same year at Yosemite.

Members of the profession undoubtedly continue to maintain a deep interest in all plans which aim to better the conditions of hospitalization and medical service to those citizens who, because of insufficient income or other reasons, face serious financial and other problems when afflicted with unforeseen illness. On the other hand, there is a widespread and accepted belief that, because of the far-reaching social welfare factors involved, the solution of such medical relief problems as may be challenging both the profession and the laity, must come about through evolution and trial, and not by some of the revolutionary procedures advocated in the academic discussions of the subject. The delegated representatives of the profession, in meetings of the House of Delegates at Coronado, gave expression to their interest in methods of medical practice, through resolutions then submitted. Basing judgment on the votes they gave, there can be little doubt on how goodly a majority of the delegates stood respecting matters of further experimentation with expensive and unsatisfactory surveys, which thus far have led to little more than a startling dissipation of resources which the Association had slowly accumulated in previous years.

---

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

The conversations among delegates and attending members gave evidence, too, of the general thought now held by members of the profession, that, while there has been a tremendous agitation on paper, and in the minds of a small number of laity and physicians, concerning the amount and kind of medical and hospital care needed by a limited portion of citizens belonging to the lower-income bracket groups, the propaganda so carried on by some of the proponents of certain health insurance plans had gone to extremes; and that the remedies advocated were not adapted to achieving desirable ends for either the lay public or the medical profession. The Coronado delegates gave no indication of desire to pursue, at the expense of the Association's members, further will-o'-the-wisp or other surveys which, if really needed, might well be carried out through federal, state and local public agencies, rather than at the expense of our physicians, through their constituted organizations. It may be added, also, that, among the majority of the delegates, there was a strong feeling of regret that the delegates who were members of the previous sessions of the House of Delegates should have embarked the Association upon expenditures far in excess of those first proposed and estimated by the salaried survey staff; running, indeed, into so massive a sum of the Association's funds as to be in excess of fifty thousand dollars. Now, that so much has been spent, and there is so little to show therefrom, the realization of what is construed as hasty and ill-advised action becomes more and more apparent. Unfortunately, this change of mind does not bring back, into the Association's treasury, the thousands of dollars expended upon the adventure.

* * *

Practice of Medicine by Corporations, and Inclusion of Medical Services in Hospitalization Insurance Plans.—On the question of medical practice by a corporation—whether the corporation was owned or managed by laymen or members of the medical profession, making no difference—and also on the inclusion in hospitalization insurance plans of any type of medical work, such as x-ray or clinical laboratory service, the House of Delegates affirmed the stand taken by the American Medical Association at its recent Kansas City session; thereby placing on record the California Medical Association equally and unequivocally against such abuses.

Because of the much increased interest that is shown in hospitalization insurance plans, Assembly Bill 246, now having a place in the statute books of California as Chapter 386, and known as the Nonprofit Hospital Service Bill, is reprinted on page 109 of this issue. Many members of the Association may wish again to read this statute.

* * *

Why State Association Dues Were Increased.—The depleted condition of the State Association treasury, and the imperative need of having funds on hand to enable the organization properly to do its work, led the Council on Monday evening, May 25, to recommend that, for the year 1937, the state assessment be increased by five dollars. The recommendation was referred to the Reference Committee, and its report to the House on Wednesday evening also being in favor, and no delegations or delegates opposing, the assessment was ordered by unanimous vote. Some of the special expenses which it may be necessary to meet in the next two years are publicity campaigns to combat the initiative to open county hospitals of California to all citizens, without regard to their financial status, and the fighting of vicious public health legislation which will probably be brought forward at the next session of the legislature, convening in January, 1937; and also the carrying out of instructions from the Yosemite House of Delegates to place a qualifying certificate (basic science) initiative on the ballots in the state election of 1938, as a deterrent to additional examining boards in cultist and sectarian medicine. Appreciation of important issues such as the above explains the unanimous vote that was given to the change in the state membership assessment.

* * *

New By-Law on Disciplinary Procedure.—Because, during the last several years, two or three component county societies have had rather bitter experiences in their efforts to discipline certain members charged with having been engaged in unethical conduct, the Council of the State Association, realizing the need of an authoritative and exact procedure when disciplinary problems are involved, appointed a special committee to submit such a code to become a part of the by-laws of the State Association, and thus, automatically, also a part of the by-laws of every one of its component county units. This by-law will be incorporated in a new edition of the constitution and by-laws ordered by the Council. Officers and members of component societies are advised to read this new by-law and, in any contemplated disciplinary action, meticulously to govern themselves accordingly. It appears in the minutes of the House of Delegates printed in this number of California and Western Medicine (on page 80).

* * *

Proposed Amendment to the Constitution. A proposed amendment to the constitution, providing for safeguards against future undue expenditures, was the result of a recent sad experience in trying to fulfill instructions given at the Riverside and Los Angeles sessions of the House of Delegates and drawing on the State Association's funds to make the medical costs survey—with no top-limit on the amount of money so to be expended; and this proposed amendment* will come before the House of Delegates at the annual session in Del Monte, 1937.

* * *

All Features of the Coronado Session Were Up to Standard.—These comments on some of the happenings at Coronado are made especially for readers who do not wish to go through the maze of official proceedings as chronicled in the stenographic minutes.

The scientific exhibits were fully up to standard, and the commercial displays likewise happily placed. The near-by San Diego Fair, with its admirable Hall of Medical Science, provided additional social features. The dinner to President Peers saw the spacious dining rooms of the Hotel del Coronado filled to overflowing; and roomy rotundas and porches of the famous caravansary gave all present opportunities without end to meet old and new friends.

In conclusion, it may again be confidently stated that the Coronado annual session was, in its series of meetings of real inspirational value, in every way a great success; and those who were not in attendance may now turn their thoughts to the possibility of participating in next year's session at the Hotel Del Monte in Monterey County.

SUMMER COMMITTEE WORK IN COUNTY SOCIETIES — PREPARATION OF FALL PROGRAMS: COLLECTION OF COUNTY SOCIETY HISTORICAL MATERIAL

Summer Vacation Periods May Be Utilized Advantageously by Committees.—Most county societies discontinue regular meetings during the summer vacation months, the members coming back with increased zest and interest when the scientific meetings resume in the fall. Experience has shown such arrangement to be desirable, but experience has also demonstrated that county society committees, whose members may occasionally meet with one another during these breathing spells, can well plan work sure to enhance the society proceedings when, in the succeeding months, their reports will be submitted.

* * *

Program Committee Should Plan Its Work to Cover the Year.—One such committee whose members have a very definite responsibility is that "on program." A county society profits greatly if the committee on program plans a coordinated group of papers, assigning authors for the topics, so that certain themes of general or special local interest are developed in rounded and instructive form. Of importance, also, is the presentation of patients and specimens in such wise as to elicit stimulating debate; which again brings to mind the advantages to be derived in discussion, when authors submit, in advance of the meetings, their papers to two or three colleagues, with a request that they be prepared to discuss certain phases when called upon by the presiding officer. Hastily gotten together or impromptu medical programs occasionally do measure up to a good standard; but, in the long run, that society has the more valuable meetings whose program committee properly fulfills its functions by carefully planning in advance.

* * *

The Sadly-Neglected Historical Studies of Our State and County Associations.—Another committee which every county society should appoint is the Committee on History, the society secretary being an ex officio member thereof, because he is supposed to be in possession of the organization's records. It is a sad reflection on most of the county units, and even upon the state organization, that so little concerted and result-producing effort should have been made in the past to gather together old record books and other memorabilia which could be utilized as a basis for one or more historical papers for the local societies; copies always being sent, of course, to the State Association for preservation in its own archives. During the coming year the State Association Committee on History aims to start a consistent campaign that will promote the furtherance of historical investigation. The presidents of county societies which do not have history committees are requested to appoint those, or to ask for volunteers, who will start this work during these summer months. If nothing more were done than to find out whether a complete set of secretary records are still in existence, and where they may be found, that in itself would really be something. As a further suggestion, it might be wise to gather together all old record books of county societies and forward them to the State Association offices at San Francisco, where they could be kept for safe keeping and reference, as needed. If some such plan is not followed, then, as in the past, it will become only a matter of time when a local secretary may forget to turn over the old record books, and so allow them to be forgotten and irretrievably lost.

Our State Association was founded in 1856, but, as with so much else in the annals of California, the written records of early days in our possession are practically *nil*. Another instance of our lack of thought for the cultural-historical may be found in the interesting biographical notes, for the first time published in California and Western Medicine, in its May and June issues, concerning Dr. Joseph P. Widney, who in 1871 founded the Los Angeles County Medical Association, and is still active at the age of 95, in literary and other work. His part in the establishing of the largest county medical society west of the Mississippi, as well as his living presence was practically unknown to a majority of members of that large and important county unit. We must all agree that such indifference to the historical backgrounds of state and county organizations, which for almost a century have carried on the battle for proper standards of medical practice and public health in California, does not redound to our credit. Before it is altogether too late, then, let us set about, in earnest fashion, to take up this work, lest those who will follow in our footsteps may cast reproach upon our memories.

---

* The amendment has a place in the minutes of the House of Delegates (page 92).

DEATH OF DR. CAMPBELL P. HOWARD, GUEST SPEAKER AT THE CORONADO ANNUAL SESSION

Among the distinguished guest speakers at the Coronado annual session was Dr. Campbell Palmer Howard, for years professor of medicine in the McGill University Faculty of Medicine, at Montreal, Canada, who presided at the clinical-pathological conference on Tuesday, May 26, and in such a manner as to elicit the admiration of all who were present to profit from his inspiring leadership. Having been so invited by the California Medical Association to come afar to this year's session and assume this duty, he met his obligation cheerfully, although sufficiently suffering physically at the time to keep to his bed, in the hotel, until almost the hour of his clinic.

Members of the California Medical Association, therefore, will learn with the greatest regret of Doctor Howard's sudden death several days later (on June 3), while on a visit with an old friend and colleague.*

The sympathy of the California Medical Association is here expressed to the members of Doctor Howard's family and to his colleagues on the faculty of McGill University.

PRACTICE OF ANESTHESIA: CALIFORNIA SUPREME COURT DENIES APPLICATION FOR REHEARING

On page 461 of California and Western Medicine for June, reference was made to the opinion handed down by five of the California Supreme Court justices, permitting, in essence, an unlicensed person to administer an anesthetic to some other person, and so to practice medicine, provided that the giving of the anesthetic "was and is done under the immediate direction and supervision of the operating surgeon and his assistants." A footnote to our comments stated that the Council of the California Medical Association had instructed its legal counsel, Mr. Hartley Peart, to make application to the Supreme Court for a rehearing. This was done, a brief being prepared in regular form. Lack of space prevents its publication in the current issue, but in a subsequent number we may again refer to the subject. On June 15, the application for a rehearing was denied by the Supreme Court, only Justices Langdon and Curtis voting in the affirmative. This means that the original opinion of Justices Waste, Conrey, Curtis, Langdon and Thompson of the California Supreme Court, sitting in banc on May 18 last, is now law.*

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 69.

EDITORIAL COMMENT†

THE PHYSICIAN AND THE DRUG TRADE

When Edison, Bell, Marconi, DeForrest, and the other great wizards of modern invention were developing their marvelous ideas, caution marked their efforts at every step, and proven safety and efficiency were their guiding principles. No incomplete, half-baked products were prematurely exploited for the sake of possible profit. Exactness and practical utility were accepted as basic requirements of scientific procedure.

Not so with many manufacturers of new drugs. Here, since nothing more than the unimportant issues of life and death are at stake, commercialism instead of proved merit seems to dominate the situation.

The question may be seriously raised whether present-day medicine is truly progressing, unless "progress" is used in its generic sense as meaning simply movement, which may be backward as well as forward.

Is medicine really progressing in the direction of accuracy, definite improvement in the remedial agencies employed? A glance at the record of the past few years would seem to make it very clear that the matter is at least a debatable one. And this without special emphasis upon the professional or economic phases of the subject. The trend along these latter lines is certainly not toward forward progress—even the confirmed optimist would admit as much. And, viewing the question dispassionately, a similar possible conclusion suggests itself with reference to the administration of drugs. Of course, we all recognize that improvements of far-reaching value have been made in the discovery of new remedies and methods of treatment; but these are usually so deeply buried under a veritable avalanche of commercial novelties and nostrums that the items of honest merit are often wholly obscured.

---

* California and Western Medicine for June reprinted, on page 534, a brief newspaper item about his death. In this issue the proper obituary notice will be found on page 102.

* The full opinion was printed on page 537 of our June issue.

† This department of California and Western Medicine presents editorial comment by contributing members on items of medical progress, science and practice, and on topics from recent medical books or journals. An invitation is extended to all members of the California and Nevada Medical Associations to submit brief editorial discussions suitable for publication in this department. No presentation should be over five hundred words in length.

So rapidly has science announced new truths that the world has been utterly unable to assimilate them. In the frantic effort to keep pace, industry has suffered all but total collapse. And in the domain of living organisms a similar deluge of new truth has left biology, chemistry, and physiology floundering. Result: unwarranted conclusions, deductions immature, often misleading, sometimes even absurd, have poured forth in endless profusion, and the poor credulous physician spins around like a pup chasing its caudal appendage in his futile efforts to keep up with the procession.

New hormones, vitamins, and all kinds of fantastic panaceas, singly and in impossible combinations, released in ever-increasing number by laboratory technician and trade organization, have become perfectly bewildering in their number and variety. Today the profusion of remedies bears close resemblance to a tropical jungle, with its lush undergrowth concealing and smothering the occasional beautiful orchid.

No human mind is competent to remember and intelligently apply the resultant conglomeration. A heterogeneous mess of good, bad, indifferent, and actually harmful, is thrust upon, and threatens literally to engulf us. Anedemin, karicin, panodyn, jeculin, incretone, sedobrol, glykeron, pneumophthisin, ergoapiol, endocrine compound No. 4 (or 404), anti- this and pro- that, etc., *ad nauseam et ad infinitum.* These, cited at random, are a few, a very few, of the fancifully named products that we are besought and instructed, at the sacrifice of much of our office time, to bear in mind and perpetrate upon our confiding patients. And the crop seems inexhaustible. The total cost involved in printing, postage, samples, and salaries would undoubtedly make a considerable dent annually in our huge national debt. Somebody must pay this cost. Trade does not operate on a philanthropic basis.

Nor is the manufacturing purveyor the only culprit. When he stops to think, the physician must realize that the retail drug and department stores do more prescribing in every community than the entire medical profession. If the customer does not call for them by name, the smug irresponsible clerk, or smiling "saleslady," glibly suggests that aspirin is "good for" headache, bromoquinin for colds, or crazy crystals for constipation. Reliable figures regarding this evil would disclose some startling facts. Startling—but in most instances precisely in accord with the business office rackets of the trades people.

The question is a pertinent one. Whither are we headed, forward or backward?

SLEEP DISORDERS IN CLINICAL PRACTICE*

PART I

By Franklin G. Ebaugh, M.D.†
Denver, Colorado

Disorders of sleep are among the commonest complaints which a general practitioner is called upon to treat. One writer estimates that 30 per cent of office patients have some type of sleep disturbance.[1] Our own experience in psychiatric practice would corroborate this, as most types of mental illness have some form of insomnia. It is now recognized that the treatment of those insomnias which are not toxic-organic, or environmental in origin, carries one into the midst of psychiatry, where a knowledge of personality function is essential. This is not as formidable as it may seem, for only a common-sense approach, free from both entangling theories and a complex vocabulary, is offered. We begin by asking "What is sleep?" The multiplicity of definitions reveal the fact that the exact nature of the process is unknown. The simplest definition, "the state of minimal normal activity, both organic and psychic," [2] tells us little, but has the advantage of not implying the action of a specific mechanism which might commit us to an unverified belief. It definitely implies that the entire body with all its systems participates in a normal process in a normal way; that any theory which regards sleep as an abnormal state is erroneous. That sleep is only a diminution of immediate activity was suggested by G. T. Fechner in 1860. Evolutionary studies, so fruitful in other fields, do not help us much here, even though we consider sleep as the result of a slow evolution of activity rhythm up the biologic ladder.[2,3] Purely psychologic studies on dissociation, reception of stimuli, dream-life, and somnambulism also offer no real explanation, however interesting some of the findings may be.

The literature is rich with painstaking observations of the behavior of the body systems during sleep.[1-42] Since most of these facts will not be pertinent to the present discussion, we will not attempt a summary except to discuss the effects of loss of sleep.

EFFECTS OF LOSS OF SLEEP

There is widespread among the laity a profound belief that loss of sleep predisposes the victim to "insanity," or to poor health. It is necessary to combat this belief vigorously at the outset, in order to carry on treatment rationally. Indeed, such reassurance, supported by well-chosen examples, may often allay much apprehension and make the remainder of the treatment simple, for some insomnias center about fear of the ill effects of loss of sleep. What are the effects of prolonged loss of sleep? It is difficult to find well-authenticated cases in human beings who are not experimental workers testing themselves under controlled conditions, because the reports given are too vague to be reliable. Kleitman voluntarily deprived himself of sleep for 115 hours without finding any marked biochemical changes.[27-29] Patrick and Gilbert, Robinson, McDougall and Smith, and Herz are other experimenters who report the results of loss of sleep for eighty to one hundred hours without any noticeable physical changes or decreased efficiency in the performance of varied mental tests.[13] So long as these men kept active they seemed to be as competent as they were during a normal day; it is difficult to determine the effect of their interest on their performance. It would seem from the evidence presented by these men that sleep is merely a luxury. Another group, Johnson, Swann, and Wiegand, however, conclude that the tests used do not adequately measure the undoubted changes which are present. A recent study, the case of Mr. Z., is interesting in that the subject voluntarily deprived himself of sleep for 236 hours (ten days).[25]

---

* From the Colorado Psychopathic Hospital and Psychiatry Department, University of Colorado.

† Guest-speaker address, read before the California Medical Association, Coronado Beach, May 27, 1936.

This man, like all the others reported, recovered promptly following a twenty-four-hour rest. Common experience also indicates that there is no so-called "sleep deficit," *i. e.*, that additional sleep is necessary to overcome the effects of prolonged loss of sleep. Instances of great productivity, combined with good health and longevity, may be cited to the patient; examples are Napoleon, John Wesley (the founder of Methodism), Thomas Edison, the inventor, and Pareto, the Italian sociologist. Several experiments in the reversal of sleep rhythm even point to the possibility of increasing the length of the working day by sleeping from 7 p. m. until 12:30 a. m., when sleep is supposed to be most efficient. It is claimed that persistence in this routine enables a person to become habituated sufficiently well to maintain a high level of efficiency.[43] It is suggested that in the future planned sleep to increase productivity may become common.

THEORIES OF SLEEP

The many theories of sleep are summarized as follows:

Cerebral Anemia (Alcmeon, fifth century B. C.; Blumembach, 1795; Mosso, nineteenth century; Howell, nineteenth and twentieth century).

Osmotic Theory supposes that water enters into the nerve cell as a result of the functional activity, thereby decreasing its excitability. (Rosenbaum, Devaux.)

The Dendritic Retraction Theory supposes that the contact between the dendrites is broken, and presumably associative brain processes are interfered with. (Duval, 1895; Cajal, Lugaro.)

Toxic Theories — Burton, "Anatomy of Melancholy." Pieron, the most able representative, believes in a "hypnotoxin." Others believe that lactic acid, cholesterin, CO_2, "leucomaines" (unoxidized products obtained from muscle), "neurotoxins," may be the specific agent involved.

Endocrine Theory—Salmon believes that sleep is a secretory function of the hypophysis.

Sleep Center Theory assumes a regulatory function exercised by the diencephalon. Supported by much experimental and clinical evidence.

Sleep as a function of different levels of the organism which are dissociable. (Kleitman.)

Sleep as inhibition. (Pavlov.)

KLEITMAN'S THEORY OF SLEEP

Kleitman correlates the following facts into a theory of sleep:

1. Sleep is an easily reversible activity of the highest functional centers of the cortex.
2. The inactivity is due to a functional break between the cortex and lower centers.
3. The break results in a decreased number of afferent impulses from the sensory organs, especially those of proprioception which may become fatigued.
4. In the absence of such fatigue, voluntary or involuntary relaxation may produce the same effect.
5. Diurnal wakefulness and sleep is a conditioned phenomenon.
6. Sleep can be correlated with a decrease in muscle tone and decrease in body temperature.

This view (Kleitman and Pavlov) is more attractive than the others presented in that it postulates cortical activity or lack of activity as an integral part of the sleeping process. We definitely feel that even though the actual physiology of sleep is not understood, it is a definite vital function engaged in by the personality as a whole, including all levels: structural, physiologic, endocrine, autonomic and cortical, and that most sleep disorders must be treated on the level at which they occur, *i. e.*, the highest integrating or psychobiologic level.

DISORDERS WHICH CAUSE SLEEPLESSNESS

We now turn to the various disorders which cause sleeplessness. A conveniently simple clinical classification is:

I. Environmental causes.
II. Psychobiologic causes.
    (a) Toxic-organic.
    (b) Personality malfunction.
        1. Psychoneurosis.
        2. Affect disorders.
        3. Content disorders.

Environmental Causes.—Environmental causes are important to keep in mind, because much patience and perseverance are necessary to discover these causative factors when investigating a case. It would obviously be unnecessary to treat a personality disorder when moving into a quieter apartment would cause cessation of the complaint. Besides noise of all descriptions, one considers the possibility of an unsatisfactory bed, mattress or sleeping arrangements; too much warmth, too heavy covers, odors, lights, drafts or other poor ventilation, improper humidity, and even altitude. Habituation is important in the latter case, as can be attested to by some who have experienced sleeplessness due to marked change in altitude. Temperature and humidity, likewise, offer problems of habit training, as exemplified by travelers in the tropics.[2]

Toxic-Organic Causes. — We emphasize the toxic-organic causes because every patient should have the benefit of a thorough physical examination to rule out the possibility of somatic pathology. Organic disease may cause sleep disturbance due to pain, distress, discomfort, tension, fatigue, toxemia; or from the secondary emotional effects, such as anxiousness, preoccupations, worry and feelings of depression. Such factors will be easily apparent in most diseases, but sleeplessness may be one of the earliest complaints in hyperthyroidism, the avitaminoses (beriberi, pellagra, Korsakow's syndrome), syphilis, including paresis, postencephalitis, arteriosclerosis, hypertension, cardiac disease, and cancer. Hypothyroidism is generally said to produce somnolence, but sleeplessness was found by Watkins in 6 per cent of his cases.[1,44] Insomnia, or a mild stupor, may be the presenting complaint in obscure cases of subdural hemorrhage weeks after the injury. Hunger pangs, mild hypoglycemia, and obesity may be causative factors. The latter often causes physical discomfort, but may also be a clue revealing too large an ingestion of an evening meal, or a relative myocardial insufficiency. Theoretically, fatigue causes insomnia by increasing the number of tonic discharges, thereby removing the optimum conditions for relaxation and sleep.[28] The ingestion of tea, coffee, tobacco, alcohol, or carbon monoxid are possible causes of insomnia in certain people. That there is wide variation in individual susceptibility is well established.[1,10]

Encephalitis and Sleep.—A few words on encephalitis are in order, since the observation of this disease has taught us much about sleep disturbance. The somnolence which may be found here is usually associated with lesions of the floor of the third ventricle; tumors and trypanosomiasis in this location also cause sleepiness. These lesions cause a paroxysmal type of somnolence, usually free from torpor and dulling of the sensorium if there is no increased intracranial pressure, which is indistinguishable from normal sleep, and from which the patient can be awakened to full consciousness (Fulton and Bailey). There is no rational treatment. The insomnia caused by encephalitis does not seem to harm the patient. Like the insomnia of other organic diseases of the brain, it is very difficult to induce sleep in these patients even with large doses of hypnotics. Reversal of sleep rhythm was a pronounced finding in the great epidemics of 1917 to 1920.

Narcolepsy. — Narcolepsy, the "condition of which the main or even the sole symptom is the occurrence in the daytime of paroxysmal attacks of a state closely resembling sleep,"[2] has been classified by Wilson[50] as follows:

1. Recurring diurnal attacks of sleep, (*a*) with attacks of tonelessness; (*b*) without toneless attacks.

2. Sleep attacks of continuous duration, day and night slumbers merging into each other, continuous sleep.

There is a third possible subdivision, namely, attacks of tonelessness without sleepiness that has been seen by Wilson. He believes that the narcolepsies are no more a single disease entity than the epilepsies, and the cause no more known. He groups the causes under the following: (1) traumatic; (2) psychopathological; (3) endocrine; (4) epileptic; (5) toxic infective (encephalitis); (6) circulatory; (7) tumors; (8) idiopathic. Treatment should be directed against removal of possible causes. Large doses of ephedrin may abort attacks, and are the best known remedy for the sleepiness. Benzedrin is now being offered as a more efficient drug, since the effects are supposed to be less toxic and more prolonged. (Narcolepsy, Prinzmetal and Bloomberg, J. A. M. A., 105, 2061, Dec. 21, 1935.)

PERSONALITY MALFUNCTION

The next large group of causes are those due to some degree of personality malfunction. These may be severe enough as to constitute a major psychosis, in which case treatment should be directed by a competent psychiatrist and usually in a psychiatric hospital. Those personality disorders which cause persistent symptoms, but do not disrupt the integrity of the individual or unfit him for ordinary society, are known as minor psychoses or part reactions. In the strictest sense, true insomnia is due to a part reaction. The more important types of part reactions seen are:

1. *Personality problems* as expressed by hysterical, hypochondrical, obsessive-compulsive, or neurasthenic complaints.

2. *Affect disorders,* in which the mood may be sadness and melancholy or elation.

3. *Content disorders,* with expressions of impure affects like fear, suspicion, anxiety, or generalized tension. These may border on the more malignant types with true delusional systems and hallucinations.[38]

PREFERABLE PLACES FOR TREATMENT

Before discussing treatment in detail, it may simplify the problem to mention that often a preliminary survey will be necessary to decide if the patient can be treated as an ambulatory case or as a patient in his own home, or whether removal to a general or psychiatric hospital is advisable. The principles of treatment will be the same in all cases, but the actual management will differ widely on this score. Each case must be decided on its own merits. Most "complaint disorders" or "part reactions" can be cared for through office interviews; the few persons whose ailments cannot be handled in this way should go to a sanitarium or psychiatric hospital, where the routine environment may be rigidly controlled. Major psychoses usually require psychiatric care in a hospital. Toxic-organic disorders must usually be treated in a hospital, where good nursing care is available. The severe deliria need care in a psychiatric hospital.

TREATMENT OF A PERSONALITY PROBLEM

The treatment of a personality problem begins with an extended study of the individual by means of the techniques taught by Adolf Meyer and his colleagues, after thorough physical, neurologic and laboratory examinations have ruled out all possible toxic-organic causes. Environmental causes will usually present themselves in the complaint and the history, and will suggest their own treatment.

The first step in this procedure is to investigate the complaint of the patient in every detail.[37,38] We ask: Exactly how does this patient suffer from sleeplessness? What are his sleep habits

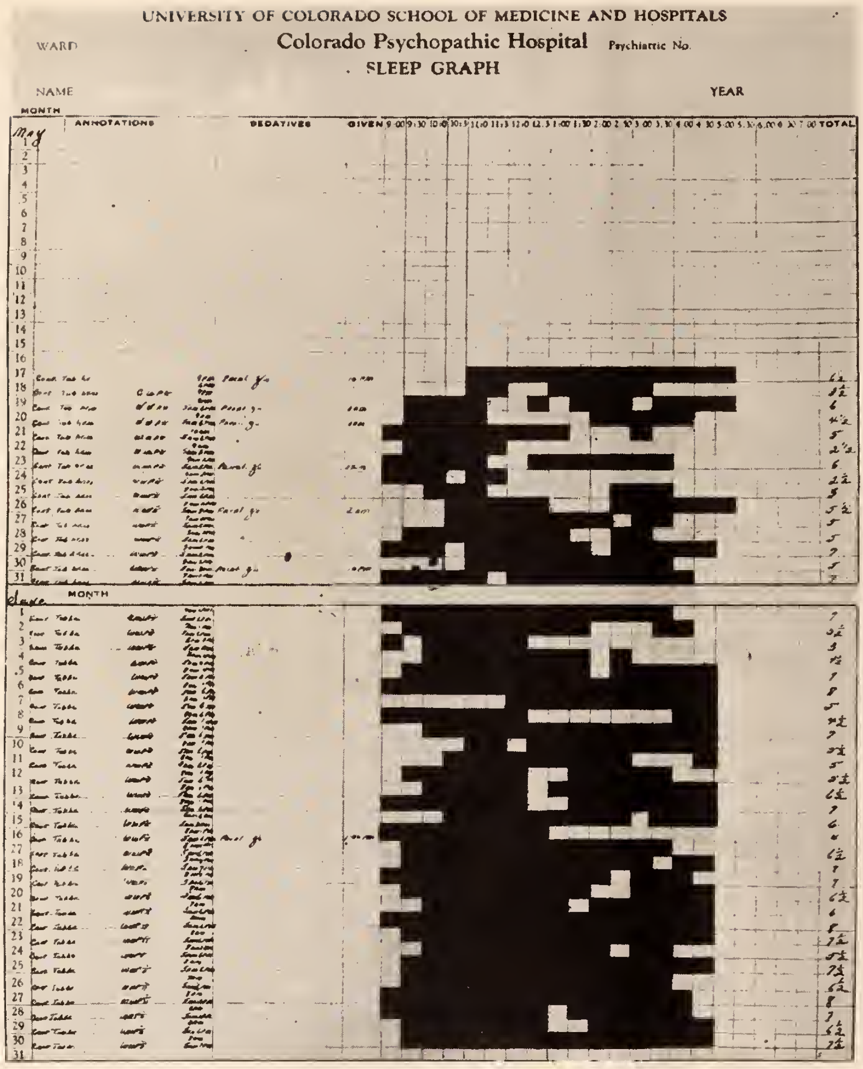

Chart 1.—Showing irregular broken sleep in a manic-depressive psychosis, manic type. Reliance on paraldehyd for short period, continuous baths and warm wet packs.

and how have they been disturbed? Is there early morning waking as in depressives, or reversal of sleep rhythm as in arteriosclerotics and some encephalitics? What are the disturbing factors? When did the complaint arise, and in what setting? What concomitant factors (social, financial, physiologic) causing unrest are present? What is the content? These leading questions and others which they suggest, when answered in quite specific detail, will usually reward the physician with a clear picture of the complaint. This type of investigation may be as precise and "scientific" as any other clinical or laboratory procedure.

We now proceed to find out more about the person who is suffering from the complaint. To this end we follow a systematic inquiry regarding the developmental history; the social and intellectual history; the religious, familial, occupational, and other special interests; the personal habits; the past personality and the family history, so that a broad picture of this patient in action is obtained. If necessary, corroborative information is obtained from relatives and associates. When all this is thoroughly done, one can trace the onset and gradual development of the disorder both in relation to the deeper causative factors present in the patient's personality as well as to the immediate precipitating factors. We attempt to reconstruct the moving drama of the whole person, breathing, acting, willing, working out his destiny as he may without artificial division into a biologic or psychologic body. We recognize an integrated personality consisting of many related part functions, any of which may be out of order and causing the whole to suffer. In order to control this maladjustment the facts of the life record must be organized in a trained, skillful manner, so that they will be useful for therapy, for each case is unique and will dictate the manner in which it is to be treated. Commonsense procedures are employed to help the maladjusted patient reorganize his manner of living in such a fashion that the complaint will disappear. After an affective *rapport* has been established between the physician and the patient, based on the latter's confidence and respect which have been enhanced by the impressive methodical investigative procedures outlined, one may employ *aeration* or *ventilation* of the conflict material presented, either by direct interviews or in unusual cases by means of special methods such as hypnosis and sodium amytal interviews. The important thing is that the patient is given a chance to discharge and bring out in the open all of those life experiences which have been causing him concern either more or less consciously. Where one discovers an unusual emotivity either from the history, the Jung-association test or the association-motor test, one may *desensitize* the patient to the painful situation by repeated interviews until he can face the unpleasant realities as frankly and as honestly as possible. This procedure is especially valuable in the symptomatic treatment of fear reactions. A planned *reëducation* is gradually worked out by mutual participation between the physician and the patient; as the latter develops a clear insight into the mechanism of his illness, he establishes new habits of response to noxious stimuli, and formulates an adequate industrial, social, recreational and activity program to insure future stabilization. *Reassurance* is given as needed, but dependence upon the physician is to be gradually discouraged, since it is the ultimate goal of the medical profession to make itself unnecessary. In addition, it may be advisable to treat the patient's relatives and reëducate them into new habits of response toward the patient.

The above procedures, to be carried out intelligently, require that every individual case be formulated in terms of its causative factors in such a way that those factors which can be modified are emphasized and become the center of attention. Factors which cannot be altered are recognized as such and the patient is trained to tolerate them. We have found such procedures to operate successfully in the large majority of our cases.

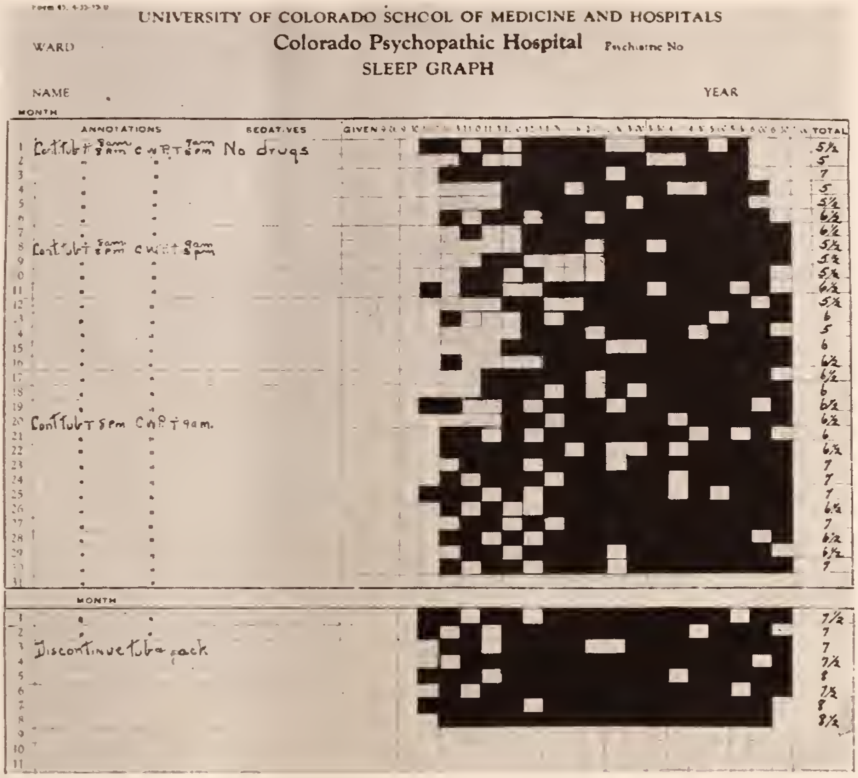

Chart 2.—Psychoneurosis, anxiety state, showing difficulty in falling asleep. No drugs used, continuous baths and cold wet packs employed.

PHIPPS' PSYCHIATRIC CLINIC CHARTS

There are few good classifications of the sleep disorders as such, so we will limit ourselves to pointing out those types of sleep disturbance which are somewhat characteristic of the disorders in which they occur. The charts devised at Phipps' Psychiatric Clinic are a valuable aid in describing those disturbances.[38,45] (See Charts 1 and 2.) We employ them at our hospital (Colorado Psychopathic Hospital) in all cases where the insomnia is difficult to control, in order to obtain more exact information about its nature. The nurses note on a special chart at half-hourly intervals whether the patient is asleep or awake. Special procedures or medication are also recorded, together with any pertinent information describing the nature of the sleep. Muncie[37] lists the following advantages and disadvantages of the chart:

1. It gives immediate information concerning the time and duration of sleep.
2. It gives an immediate correlation between sleep and hypnotic medication.
3. It leaves room for marginal annotations, and cross references to other parts of the history, *e. g.*, the behavior chart, the pulse and temperature chart.
4. It is concise, one sheet of the size of ordinary history paper giving space for two months, and adds little bulk to the history—a matter of no little importance.
5. Its use involves no change in nursing procedure.
6. The recording is easy and takes little of the nurse's time. It has several disadvantages:

(*a*) It is based merely on our half-hourly type of recording.

(*b*) It gives no information regarding depth of sleep.

(*c*) It gives no information concerning the condition and activity when the patient is not asleep.

The nurse's notes kept nightly on each patient have to supplement the record.

In general, relaxed posture, deep, regular respiration (and snoring), unresponsiveness to environmental stimuli, have to serve as criteria for sleep. Fairly uniform dependability is attained.

HOW CHARTS ARE USED

From these charts we can correlate certain types of sleep disorders with the type of disorder present. In the psychoneuroses, "complaint disorders," minor psychoses (merergasias), one may find difficulty in falling asleep, and intermittent sleep, often with prolonged desire to sleep in the morning (Type B). Here the content is the disturbing factor, since it is often of an anxious, fearful, obsessional or hypochondrical nature. In this group are the patients who utilize insomnia as an alibi for their failures; those who have fears regarding amount of necessary sleep; and those who fear insanity.

The affective disorders also present a characteristic picture. In the simple depressions one often finds no difficulty in falling asleep and sleeping until the early morning hours (Type A). Then the typical ruminations prevent a return to sleep. Suicidal preoccupations are often present. Together with sadness and melancholy, this type of sleep may be taken as pathognomonic of depression. An elated mood shows all types of disturbance without any definite pattern, and the patient may not sleep all night because "he is too busy."

Hallucinations of whatever type keep the patient awake because of stimulation. They may be pleasant or fear-inspiring. This is seen especially in schizophrenia.

In the toxic-organic disorders we see all types of sleep disturbances, since the content and the specific toxins make sleep very difficult. It is well known that many delirious patients do not sleep enough, so that the first requirement of treatment is to provide enough sleep.

(To be concluded)

THE PRESENT STATUS OF RENAL SYMPATHECTOMY*

By Thomas E. Gibson, M.D.
San Francisco

INTRODUCTION.—The last few years have seen a great increase in knowledge of the functions and dysfunctions of the autonomic nervous system. Major developments have occurred in the field of surgery. A number of clinical syndromes, now recognized as due to dysfunction of the autonomic nervous system, have been signally benefited by sympathectomy, among which are Buerger's disease, Raynaud's disease, Hirschsprung's disease, scleroderma, essential hyperhidrosis, essential hypertension, cardiospasm, certain types of vesical paralysis, unexplained splanchnic pain, selected cases of chronic rheumatoid arthritis, and nephralgia. The three factors concerned in disease of the autonomic system relieved by sympathectomy are: (1) excessive vasomotor constriction, (2) pain, and (3) motor imbalance or dyskinesia. The application of sympathectomy in renal surgery rests on the assumption, first of all, that sympathectomy is without harmful effect on the kidney; second, that the operation is technically feasible; and third, that there are definite indications for the operation.

RENAL INNERVATION

The kidneys are innervated chiefly by the splanchnics (Fig. 1). The vasoconstrictor component far outweighs the vasodilator in importance. The renal plexus forms a network about the renal artery, which is readily amenable to surgical attack. The nerves to the kidney are sensory, vasomotor, and motor to the smooth muscle of the pelvis, ureter, and calyces. It is evident, therefore, that (1) vasomotor spasm, (2) pain, and (3) motor imbalance or dyskinesia, for which sympathectomy has been successfully performed in other parts of the body, are potentially present to produce disturbances in the kidney which may not always be accounted for on the basis of organic lesions.

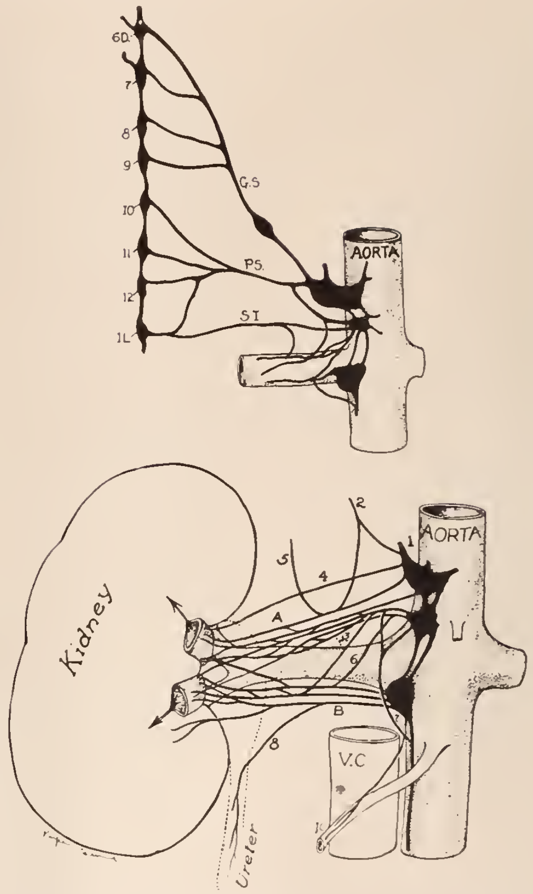

Fig. 1.—Schema of renal innervation (after Dambrin). The dorsal roots, sixth to twelfth, and the first lumbar, supply the kidney through the splanchnic nerves by way of the celiac ganglia. The renal plexus forms a network about the renal artery. The vein (shown by arrows) is not surrounded by nerves, thereby simplifying the surgical problem.

EXPERIMENTAL EVIDENCE

A vast amount of experimental work has been done to determine the effect of denervation on the kidney. Claude Bernard, as early as 1859, performed splanchnicotomy and noted the occurrence of polyuria. This work was subsequently confirmed by numerous investigators in connection with successful transplantation of kidneys, which insures complete denervation. Their results in general showed an increased secretion of urine of slightly lower specific gravity with relative lowering, but total increase in solids lasting from a few weeks to several months, explained on the basis of vasodilatation. These experiments showed that there are apparently no secretory nerves to the kidney, and that vasomotor conditions in the kidney, added to the chemical and hormonal action of substances in the circulating blood, are adequate to explain all variations and types of renal function. Other investigators who performed renal sympathectomy without transplantation came to the conclusion in general that the denervated kidney is sufficient to maintain life, even in the most severe exigencies that the normal kidney is capable of coping with, and that the operation is free from danger. Bilateral denervation in animals produced no impairment in health or renal function, and no late harmful effects were noted by the vast majority of investigators. In dogs, regeneration of the nerves occurred in from three to five months. Some experimenters found that the denervated kidney seemed better able to handle infection than the normal, as judged by urinary findings, and by the fact that more abscesses developed in the normal than in the denervated kidney following intravenous injections of attenuated staphylococcus aureus. On the other hand, certain observers found that repeated insults appeared to damage the denervated kidney more than the normal, the explanation being that loss of nervous control, with attendant vascular dilatation and stasis, lowered the resistance of the tissues to injurious agents, to which the organism was subjected repeatedly for long periods of time. Toxic agents, such as snake venom, mercury bichlorid, uranium acetate, and cantharides, injured the normal kidney less because of protective vaso-

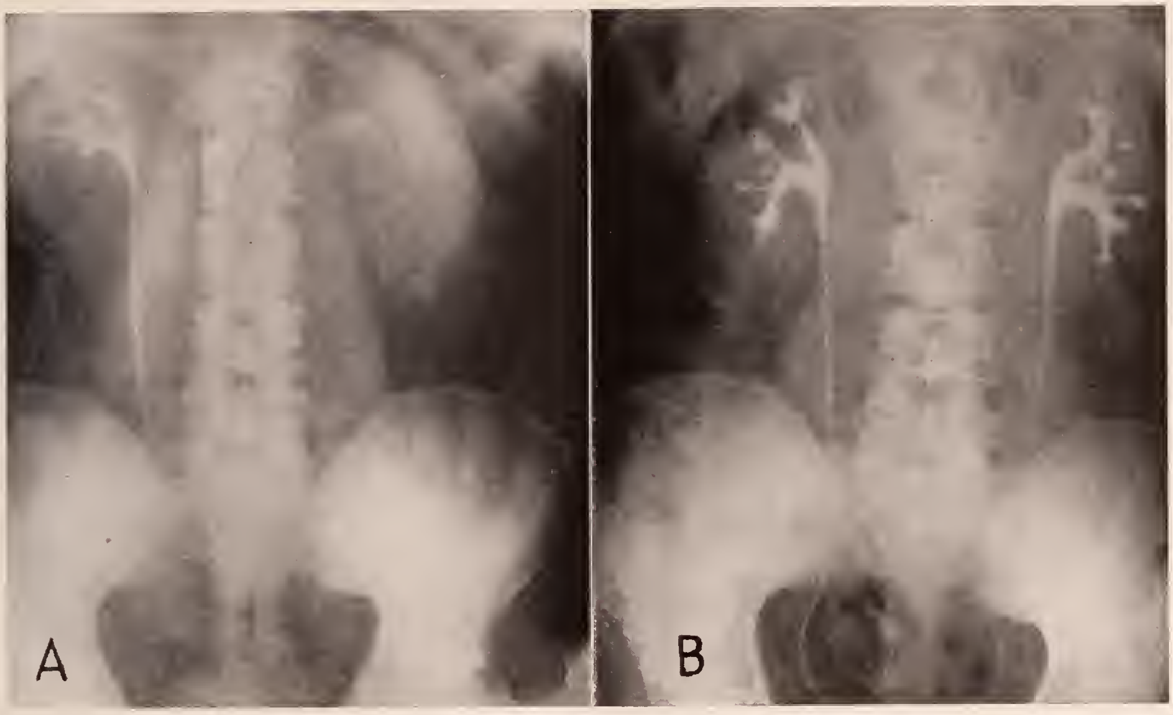

Fig. 2.—Case of sympatheticotonia: (A) Intravenous urography showing normal excretion on right, but complete failure of excretion on left, although increased density of kidney shadow shows that the renal parenchyma has taken up the excretion medium (neo-iopax). (B) Retrograde ureteropyelography with negative findings. Patient had severe renal colic, yet no organic change such as stricture, stone or irritating crystals could be found to explain the pain. The condition is apparently a spasm of the papillary ring muscles which prevents the excretion medium in the kidney from reaching the calyces and pelvis. Patient relieved without operation.

constriction. Furthermore, renal denervation had no effect on the time or amount of diuresis and loss of edema in the recovery of rabbits from uranium poisoning.

CLINICAL EVIDENCE

Clinical application of renal sympathectomy begins with Papin, who reported the first operation on a human being in 1921, and advocated it for the relief of pain due to chronic nephritis, small hydronephroses, and nephralgias of unexplained origin. Although the operation has not achieved great popularity, it has made, almost without exception, a favorable impression upon those who have had any appreciable experience with it. Increasing knowledge of the physiology of the upper urinary conduction apparatus has made it apparent that disturbances of motility (dyskinesia) may exist and cause pain in the absence of demonstrable organic pathology, and that even hydronephrosis and atony, or dilatation of the ureter, may occur in the complete absence of an obstructive factor. The term "sympatheticotonia" has been applied to these disturbances of innervation. Renal colic and nephralgias, which cannot be accounted for except on a functional basis even after the most thorough urologic investigation, fall in this category (Fig. 2). Many of these cases will respond to non-surgical treatment; but in those stubborn and inveterate cases which fail to respond, renal sympathectomy as a last resort is a justifiable procedure. Nothing is more striking and certain, according to several observers, than the relief obtained by operation in those suffering repeated, severe pain where no demonstrable pathology can be found. Sympathectomy has been advocated as a substitute for nephropexy. Nepropexy as an operation for relief of painful nephroptosis has fallen into disrepute with many clinicians, because of the frequent failure to relieve the patient's symptoms. Nephroptosis *per se* is not painful, even third degree mobility. Pain in these cases arises chiefly from interference with renal drainage. Relief of symptoms depends not on nephropexy, but on relief of obstruction existing in the form of adhesions, kinks, anomalous vessels, stricture of the ureteropelvic juncture which may be due to spasm (sympatheticotonia), actual inflammatory stricture, congenital narrowing or hypertrophy of smooth muscle at this point. If these factors are eliminated, nephropexy is of secondary importance. Renal sympathectomy, which can be easily done at the same time, is comforting to the surgeon because it makes doubly sure that pain will be relieved. Therefore, the procedure advocated in all cases of painful nephroptosis, regardless of whether some degree of hydronephrosis is present or not, is, first, to carefully dissect out the upper ureter and kidney pelvis, freeing it completely of surrounding tissues and ascertaining that the kidney has good drainage; and, second, to perform renal sympathectomy in order to make doubly sure of completely relieving the patient's symptoms. Nephropexy, then, may be omitted, except perhaps in cases of extreme ptosis.

Other conditions offering a more hopeful prognosis from the standpoint of renal sympathectomy are the oligurias and anurias of certain types of Bright's disease, as well as cases of reflex anuria

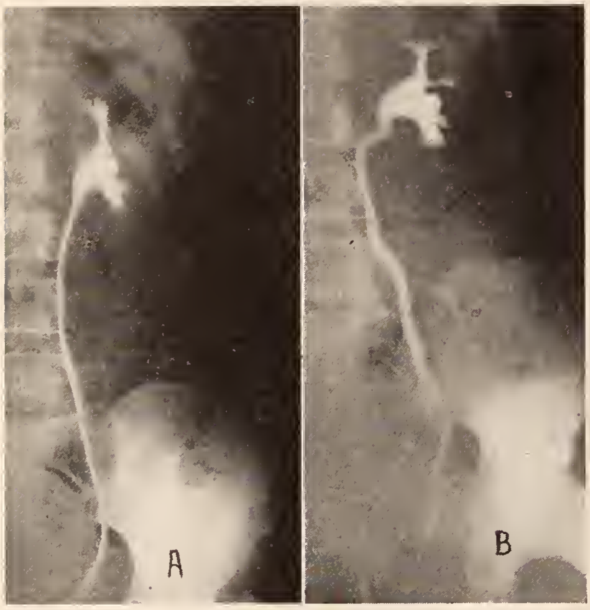

Fig. 3.—Prone (A) and vertical (B) pyelograms in patient unable to work for three years because of left nephralgia. Slight atony of left ureter. No ptosis. Pain reproduced by pyelography. Urine sterile. No relief from ureteral dilatations. Cured by renal sympathectomy.

which fail to respond to non-surgical treatment. Essential hematuria is, likewise, favorably influenced by sympathectomy when other treatment fails. It has been shown that renal sympathectomy has no effect on essential hypertension or on hypertension associated with chronic nephritis. Further investigation is needed to establish the value of renal sympathectomy in the various types of nephritis. The preliminary reports in this field do not appear to promise much except in the conditions noted above. Sufficient clinical evidence now exists to show that renal sympathectomy is not only without harmful effect on the kidney, but that even following nephrectomy the remaining denervated kidney is capable of carrying on normal renal function indefinitely, and is able to meet the demands of unusual emergencies, such as sickness, hard work, pregnancy, parturition, anesthesia, major surgery, and so on.

Personal experience, limited to twenty cases in which renal sympathectomy seemed indicated, points to this operation as one of the fine acquisitions of modern urology, to be resorted to, either alone or in combination with other essential procedures, in all cases of renal pain in which little or no organic pathology can be demonstrated.

In none of these cases mentioned was there any evidence of urinary infection, and the demonstrable pathology was slight, consisting of slight ptosis, beginning hydronephrosis, or some kinking of the ureter.

In reviewing the literature, it is singularly striking that the vast majority of cases subjected to sympathectomy have been in women. In my own series, nineteen out of twenty cases have been in the female. Why should the indications for sympathectomy show this disparity with respect to sex? I think the reason is to be found in the fact that not only nephroptosis, but also sympatheticotonia is more common in the female. The most puzzling urologic problems are to be found in the female, because so often the findings on complete urologic investigations do not seem sufficient to fully account for symptoms apparently renal in origin. Livermore (1934) has noted the preponderance of cases in women, and states that persistent pain in cases of slightly dilated pelvis and ureter is probably due to spasm, if infection and retention have been relieved. The neurotic is more susceptible to urinary tract spasm, hence more cases in women than men. Furthermore, the endocrine life of women is much more stormy and eventful than that of men. Spasm may possibly be due to many factors other than pure neurosis such as focal infection, allergy, disease of adjacent viscera such as colitis, appendicitis, gall-bladder disease, ovarian and tubal disease, and malposition of the uterus. Spasm may be due to irritating crystals in the urine or to toxins from some disturbance of metabolism. Relief depends upon removal of the cause, regulation of the endocrine system, treatment of neurotic symptoms, and, as a last resort, sympathectomy. Wharton's (1932) anatomical dissections revealed a connection between the sympathetic nerve supply of the ovary, testis, and ureter which would seem to give a sound neurologic mechanism to substantiate the hypothesis of a probable sexual foundation for certain cases of ureteral pain due to dyskinesia or spasm, in the absence of ureteritis and organic stricture. That they occur more often in women, according to Hepburn (1934) is because sexual emotional defeat occurs more often in women than in men. Usually, when a man has urinary

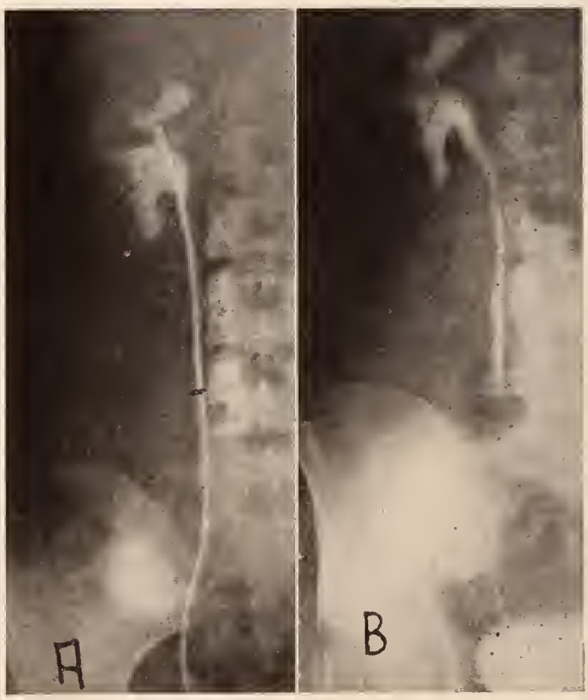

Fig. 4.—Prone (A) and vertical (B) pyelograms in patient who had right nephropexy performed eight years before. Satisfactory result of nephropexy, but pain had become increasingly excruciating. No organic pathology is evident except slight dilatation of upper major calyx. Patient completely relieved by renal sympathectomy.

symptoms a definite organic basis can be found to fully account for them. Hence, treatment offers something concrete to work on, with the expectation of completely relieving his pain without having to resort to sympathectomy. The only male in my series had a retroperitoneal lymphosarcoma encroaching on the renal pedicle and upper ureter. The ureter and pelvis were freed of adhesions and sympathectomy performed, with complete relief from further attacks of renal colic. The presence of lymphosarcoma, which eventually caused death, was not suspected until some time after the operation.

One of the most interesting cases in the series was a nurse who had been unable to work for three years because of pain in the left kidney region. A complete urologic investigation was done, with negative findings except for a slightly atonic ureter. Pyelography (Fig. 3) reproduced her pain. Ureteral dilatations gave no relief. Because of the insignificant findings operation was deferred for three years; but finally, in desperation, renal sympathectomy was done. This brought complete relief, and the patient has been able to work steadily at her profession ever since.

In another case nephropexy had been done ten years before. Pyelography (Fig. 4) showed a satisfactory result of the nephropexy, but the patient still had her pain. Sympathectomy was then done, with complete relief of pain. Such a case exemplifies the value of sympathectomy in certain cases in which nephropexy seemed indicated.

Another case of interest was a woman with right-sided pain who had an appendectomy without relief. A complete urologic investigation revealed right nephroptosis with ureteral kinking and slight hydronephrosis and pain reproduction. A combined operation, consisting of ureteronephrolysis, sympathectomy, and nephropexy was done, with complete relief of symptoms. A check-up eight years after operation showed the kidney to be in excellent position, with normal functional findings. This case is cited to show that sympathectomy produces no harmful effects upon the kidney.

Two patients had definite organic stricture of the ureter. Renal sympathectomy was done in these cases because of renal pain persisting after thorough dilatations of the ureter. Justification for the operation was found in the fact that the patients were relieved of pain. Such experiences illustrate the point that unexplained pain presumably due to sympatheticotonia may coexist with organic lesions in the upper urinary tract.

CONCLUSIONS

1. Renal sympathectomy produces no harmful effects on the kidney; it is surgically feasible either alone or in conjunction with other procedures; and in a number of conditions there are either relative or definite indications for its application.

2. Among the indications for renal sympathectomy are renal sympatheticotonia (spasm, atony, dyskinesia, hyperdynamic motility, adynamia) either alone or in association with definite organic changes (small hydronephroses, nephroptosis, painful chronic nephritis, painful adhesive perinephritis, essential hematuria, certain types of Bright's disease associated with oliguria and anuria, unyielding cases of reflex anuria, and possibly certain cases of stone forming diathesis).

3. Renal sympathectomy is recommended, in conjunction with other necessary surgical procedures, as an extra precautionary measure to make doubly sure of complete relief in any case of proved renal pain in which careful investigation reveals little or no demonstrable pathologic changes to adequately explain the symptoms.

OCULAR SYPHILIS: ITS TREATMENT*

By Hans Barkan, M.D.
San Francisco

Discussion *by H. Sutherland Campbell, M.D., Los Angeles; Julian N. Dow, M.D., Los Angeles; George H. Kress, M.D., Los Angeles.*

When one observes the therapeutic armamentarium in the office of a modern ophthalmologist, it shows very few necessary additions for the efficacious treatment of ocular diseases over the armamentarium of the year 1905, the year in which the Spirochaeta pallida was recognized as the cause of human syphilis. We use, in the main, the same small list of drugs—atropin, eserin, homatropin, zinc, silver, yellow oxid, etc.—that we were brought up to use twenty or twenty-five years ago, and have not found a new drug so specific for some one eye disease that we failed materially in not having it in 1905. Tuberculin is perhaps an exception, yet many of us feel that even in ocular tuberculosis we obtained good results without it.

SEROLOGY HAS HELPED OCULAR SYPHILIS THERAPY

In ocular syphilis, however, the therapeutic story is quite a different one. While potassium iodid and mercury were in free use before the present luetic therapy, the mode of administration was difficult, hasty, and insufficient as regards amount used. Diagnosis and treatment were based on very good clinical observation, but not subject to the check-up of present serologic methods. As a result the very distinct contrast in the number of cases of ocular syphilis observed in the material of the present day, and in that material on which I started my studies in 1912, is striking. At that time retro-orbital gummata, violent luetic iritis, fresh chorioretinitis, ocular palsies due to meningeal involvement, and numerous cases of both acute papallitis and of optic-nerve atrophies were common teaching material.

OCULAR SYPHILIS LESIONS SEEN LESS FREQUENTLY TODAY

Today we find it difficult to demonstrate to our Stanford Medical School students cases of syphilitic iritis, papillitis, or fresh chorioretinitis, and even interstitial keratitis is decreasing in frequency. In short, modern therapy, modern serological check-ups, modern social service activities, and the spread of information regarding the practical curability of syphilis, have changed the clinical picture. In addition to the varied, and in most cases effective, therapeusis in our hands, the ophthalmologist and syphilologist have learned to work together. No longer does the ophthalmologist prescribe a course of mercurial inunctions and atropin locally, to stop them when the eye for the time is well again. We rely upon syphilologists to take the case in hand and treat the individual for not only his present active syphilis, but so that he is syphilis-free regarding future danger to any of his organs before the treatment is stopped. It would be carrying coals to Newcastle to review here varied combinations used for the treatment of syphilis, no matter how expressed. Suffice to say that treatment of ocular syphilis is that of any syphilitic, with especial reference at the time of the eye infection, however, to the fact that the involvement of the eye in such a generally destructive disease as syphilis may call for certain precautions, and that involvement of certain parts of the eye has been shown to react better to one form of treatment than to another.

ARSPHENAMIN IN OCULAR SYPHILIS

Allow me to take up a few of these specific ophthalmic points. There is fear regarding the use of arsphenamin. This dates back to the use of atoxyl and its trial in syphilis. It would frequently produce a toxic amblyopia. I quote from Moore's "The Modern Treatment of Syphilis" in saying, "The condemnation accorded to it carried over unjustly to arsphenamin, was increased for a time by a misunderstanding of the mechanism of development of relapsing ocular lesions in inadequate treatment of early syphilis, and was in the process of gradually dying out when it was revived by the introduction of tryparsamid into the therapy of neurosyphilis." There are no true toxic arsphenamin reactions except conjunctival hyperemia. Very occasionally a superficial keratitis occurs, and I have noted an occasional photophobia lasting for one or two days. The Herxheimer reaction is of clinical importance only in optic neuritis or primary optic atrophy. It is rare and can be avoided by starting treatment with other than an arsenical. Personally, I would add that a central fresh chorioretinitis should be handled with caution, just as one does not care to obtain a focal reaction with tuberculin in such an instance but is not worried about an even severe flare-up on the part of the iris, ciliary body, or cornea. Once therapy is on its way, ocular relapse is not due to arsphenamin, but to too little arsphenamin.

In modern days the nontreated luetic is a rather rare visitor in the ophthalmologist's office. He comes usually with an iritis, and no manifestation of syphilis is more gratefully treated. One sees plastic adhesions and multiple papillomata of the iris disappear magically.

INTERSTITIAL KERATITIS

Interstitial keratitis is another story. Often opticians, optometrists, chiropractors, osteopaths, and even ophthalmologists, have been consulted, and yet the child has not received treatment. Treatment extending for a minimum period of two years, regardless of serological findings, does in a great majority of cases shorten the process, cause initial prompt amelioration of the photophobia and pain, possibly reduces the incidence of relapse and may decrease the frequency of involvement of the second eye. Carvill and Derby state that in sixty-two patients the second eye was involved in only two cases observed over a period of from two to five years when, in the absence of treatment, bilateral involvement would have been practically certain. These statistics, while undoubtedly accurate, are not supported by my own observations. In spite of intensive treatment I have seen the second eye involved in more than one-half the cases observed. Recently roentgen-ray treatment of interstitial keratitis has been highly praised by German investigators. I believe it may have use in those cases which have run their active course and whose dense, and still vascular, scars are radiated early, but I have had no personal experience with it. So much has been claimed for radium and roentgen-ray treatment in various diseases of the cornea, and so little has stood the test, that one may be rather skeptical. Artificially induced malaria and hyperpyrexia have been warmly praised, but their occasional danger, especially to the frequently marantic type of child, and the expense of the necessary hospitalization, speak against their standard use in interstitial keratitis. After all, in this particular manifestation of ocular syphilis, we obtained excellent results in 90 per cent of our cases in the days of mercurial inunction alone. I am not at all convinced that, except for some shortening of the process and amelioration of symptoms, mercurial inunction properly applied—I remember the children in Fuchs' clinic sitting around a hot stove until they perspired, before rubbing themselves vigorously—did not give just as good ocular results as any other method. Occasionally a vicious process is not influenced by any therapy, although I have only once seen both eyes lost in interstitial keratitis. Undoubtedly salvarsan will act more immediately upon the deeper-seated iritis, chorioditis, and optic neuritis which is almost always present.

PROGNOSIS AS TO VISION

No effect of a syphilitic infection is more totally ruinous to the individual than total blindness. Here, too, we see the less blind, whose hard fate is caused by tabetic optic nerve atrophy. We naturally are helpless in the face of a total or nearly total atrophy. No human remedy can ever be reasonably supposed to restore vanished nerve fibers. In the earlier stages, however, we no longer, as we did in Vienna in 1912, dismiss them as destined to total blindness. We refer them to the syphilologist, provided that central visual acuity is 5/10 or better and the field not too restricted. Here there is one chance in two of retaining useful vision. If the vision in either eye lies between 4/10 and 2/10, the prognosis is bad; and if less than this, there is practically no hope. Occasionally one will find a unilateral atrophic process, with good hope then of preservation of the better part of the vision of the then still normal eye, and I have seen patients with a central scotoma and little, if any, peripheral loss who, with prompt treatment, have remained stationary. If however, both eyes are equally far advanced and below 4/10 with corresponding field losses, the prognosis is bad, and this especially so if the process has been a rapid one. Intraspinal or intracisternal treatment has been the method of choice.

FEVER THERAPY IN OCULAR ATROPHY

Recently fever therapy in optic atrophy has found some enthusiastic supporters. Clark, in the last "Transactions of the American Ophthalmological Society," reports on a series of cases favorably influenced, the main conclusions being that there were no striking changes in the central visual acuity: that the Argyll-Robertson phenomenon disappeared in a small number; that vision in optic atrophy may be retained if treatment is started early enough. In cases resistant to intraspinal or intracisternal treatment, improvement may occur after malarial inoculation. Tryparsamid is to be mentioned in relation to cases of early paresis or tabes, in spite of the fact that in about 10 per cent of patients so treated ocular symptoms are met with. If they occur, it is either following the first treatment and may be a total atrophy of the optic or, with a series of treatments, consists of initial symptoms of "heat waves" in the vision or very slight dimness, and treatment must of course be immediately stopped. Fields must be carefully checked during the progress of the treatment. The risk involved from the eye standpoint may be justified in view of the good effect of this treatment in these types of cases. This was strikingly true in a patient with central scotoma, but good peripheral fields. Fever therapy, however induced, is a long and difficult process, needs most careful supervision, and can really be done well only by hospitalization. This in itself does not conduce to its use as a standard method applied to large clinical material. Many cases of tabetic optic nerve atrophy will not submit to such treatment. Unfortunately this is a disease without pain and without general symptoms. Ophthalmologists all appreciate the sometimes strikingly indifferent attitude of the tabetic with optic atrophy. He has no other complaints, is usually of stocky build and devoid of gastric crises, bladder symptoms, and ataxia, often of the ignorant type and cannot see why such a small affair as an eye needs such drastic treatment. This is only a personal observation, and please take it as such; but it is a fact that that is the sort of tabetic I have seen frequently. The highstrung, thin, rather tall tabetic with typical walk, and a cane in either hand, rarely suffers from optic atrophy.

IN CONCLUSION

In conclusion, the wise ophthalmologist will work hand in hand with the syphilologist, trust his judgment as regards frequency of dosage and length of treatment, and observe the eye frequently enough so as to be of moral support to the patient and of clinical help to the syphilologist.

Stanford University Hospital.

DISCUSSION

H. Sutherland Campbell, M.D. (1930 Wilshire Boulevard, Los Angeles).—The treatment of ocular syphilis is a matter too rarely included in a symposium on syphilis. It is a branch of the disease, the essentials of which are somewhat remote to many of us—as remote as are the varying, dimly-remembered eye-ground pictures occasioned by the different tissues of the eye which might be involved in the syphilitic process. These are visualized only by the ophthalmologist, and in similar manner the objective response to therapy is in a measure a closed book to other than those who are not only especially trained to examine the eye-grounds, but are also constantly applying the art.

When it is recognized that, of all eye involvements, only interstitial keratitis, or iritis, may commonly be visualized by us, and that "certain conditions call for advancement to therapy with a greater or lesser degree of caution," it becomes obvious that collaboration in the therapy of ocular syphilis between the syphilologist and the ophthalmologist becomes more of a necessity than an adventure.

The incidence of ocular syphilis in a thousand consecutive cases was shown by MacCormac to be as follows:

Primary	133
Secondary	172
Neurosyphilis	130
Cardiovascular	42
Visceral	14
Eye	55
Throat	112
Miscellaneous	342
Total cases	1000

So that in some sectors ocular involvement holds place over both the visceral and cardiovascular systems. It has been interesting to learn from this paper that a comparison of clinical findings in the eye, past and present, over a comparatively short period of time manifest a metamorphosis in visual characteristics which parallel those found in the skeletal and integumentary systems over a similar short period, inasmuch as the Charcots, nodular ulcerative syphilides, and massive sluffing gummas, so commonly seen in the early clinics, are today essentially rare. My last view of a group of these somewhat ancient lesions were seen at the Government Hospital Yard, in Marakeesh, French Morocco. The affected individuals were largely nomadic tribesmen, who had recently come from the outlying regions where modern therapy was unavailable. While this metamorphosis in the lesions of syphilis could be attributed to increased individual resistance, it is more prone to be due to the incidence of the arsenicals plus educational training, inasmuch as syphilis has been common to many generations preceding ours. And as race resistance is a slowly-acquired quality, it is hardly to be expected that such transformation in body lesions would occur within the space of some fifteen to twenty years.

In no other field in medicine can one find such a variety of conflicting opinions as in that of syphilotherapy. And ophthalmology has for long been concerned with the danger of the production of blindness by the use of certain arsenical preparations. Conflicting opinions are met with both as to the degree of danger in the face of certain conditions, also as to the drugs most responsible for adverse results; and this despite the stigma of blame still attached in definite measure to tryparsamid. The arsphenamins have more recently been proved harmless.

Reese, who in the face of an opposite majority contends that tryparsamid is equally as effective as malaria in the therapy of neurosyphilis, has to say in its defense "that the statement referred to in all reports, that tryparsamid is a menace to the optic nerve causing toxic amblyopia, necessitates comment. The literature reports that out of 1,254 patients treated with tryparsamid, 15 per cent complained of subjective and objective visual disturbances, with only two per cent permanent tract changes."

Beigelman, in a recent paper also emphasized the harmlessness of the arsphenamins. In his synopsis regarding the arsenicals in general he observes that, following the introduction of atoxyl, about one hundred cases of optic nerve atrophy were published. Later both salvarsan and neosalvarsan came under suspicion in connection with the many neurorecurrences, *i. e.,* optic nerve lesions following their use; but these reactions occurred only weeks after their use, and not immediately, as one would expect in a toxic reaction. They were inflammatory lesions and, therefore, due to infection rather than to a true toxic effect. The strongest proof of this lies in the fact that these neurorecurrences in the majority of cases disappeared or improved after continued therapy with the same arsenical compounds.

Young and Lovenhart have demonstrated that the toxic effect of the arsenicals upon the optic nerve is related to the molecular structure of the compounds, and that arsenicals with the amino group in a para position to the arsenic, such as atoxyl and tryparsamid, produced optic lesions in rabbits, while arsenicals with the amino group in a meta or ortho position to the arsenic, such as arsphenamin and neoarsphenamin, were totally harmless. Agreement in large measure with the present paper is shown in the statement that the answer to the question as to possible optic nerve damage, due to the use of salvarsan or neosalvarsan, is decidedly negative. Clinical experience with tryparsamid indicates that the drug has an affinity for the optic nerve, as reports on amblyopia following its use have been rather alarming. The dimness of vision met with usually occurs after the fifth dose of tryparsamid, and this clears entirely when the drug is withdrawn. It has been shown that the damage from tryparsamid may be particularly serious in extent and in permanence, when the drug is administered to patients with evidences of optic nerve atrophy. Its use, therefore, calls for careful and continuous ophthalmologic control. The important test is the perimetric study rather than the fundus examination, and once a definite change is found in the visual fields the drug must be immediately and completely discontinued. The resumption of tryparsamid, after a rest period of thirty days, as has been suggested by certain workers, is in general condemned by both ophthalmologists and syphilologists.

There are two fundamentals which may be gleaned from Doctor Barkan's very acceptable paper: first, the possibility of inducing immediate harm in certain eye conditions by means of an acute therapeutic reaction. This can readily be overcome by commencing therapy with a drug whose known immediate focal reaction is negligible Following Dr. Roy Thomas' observation regarding the safeness of iodobismitol in certain cardiovascular cases, which was given at a recent symposium on syphilis, clinical experiments were made in a few cases, demonstrating surface body lesions, and observations taken with respect to the immediate focal reactions from its use. These were found to be negligible, and the resultant healing steady and slow. It is possibly the safest drug in this respect; second, the possibility of blindness developing as a slightly delayed reaction following the use of certain of the arsenicals, *i. e.,* atoxyl and tryparsamid. In the latter case their use seems to be warranted only under the early and constant supervision of an ophthalmologist. In the event this is denied us, blindness as an end-result even in a very few cases would indicate that we are hardly justified in utilizing them, irrespective of the fact that better results might be obtained from their use in the larger number of cases.

⁂

Julian N. Dow, M. D. (1228 Roosevelt Building, Los Angeles).—Doctor Barkan has very thoroughly discussed the treatment of syphilis from the ocular standpoint, and I can do little except endorse all he has written.

With the use of arsphenamin the duration of the acute uveal inflammations, due to syphilis, has been greatly shortened and seldom is any untoward reaction noticed.

Doctors J. J. Skirball and F. M. Thurman have written of observing twenty cases that have shown neuroretinitis and vitreous changes during the course of arsphenamin therapy. Recovery occurred after the administration of arsphenamin was discontinued. The condition recurred upon resuming the treatment and again cleared when discontinued. These changes were noticed by these authors in both early and late cases. In early cases, under my observation, this has never been observed, and the shortened course of ocular inflammation, when the case is treated with arsphenamin, is most gratifying. In all involvement of the posterior segment of the eyeball, caution is to be maintained at all times and frequent observations made as to the results following each injection.

There are about fifty thousand patients in the United States with primary optic atrophy due to syphilis. The time from the onset of the ocular symptoms until blindness occurs averages from two to three years. The ocular changes may occur as an isolated phenomenon in neurosyphilis, and often little attention is paid to these symptoms by the patient until quite late in the course.

David Lees reports 613 cases of neurosyphilis, of which forty-eight, or eight per cent, showed optic atrophy. In five hundred cases of neurosyphilis with tryparsamid, he reports that treatment was stopped in five cases only because of permanent ocular damage. In his series any visual loss that was observed occurred during the first four or five injections.

Twenty-one cases of optic atrophy which were treated, with tryparsamid and bismuth, had the progress of the optic atrophy arrested for from six months to five years.

I feel that ocular fields should be taken after each administration of tryparsamid, regardless of the fact that no apparent loss is shown after the first several injections.

As Doctor Barkan has stated, "the ophthalmologist can be of assistance to the syphilologist in the observance of local reactions whenever ocular involvement is present."

⁂

George H. Kress, M. D. (945 Roosevelt Building, Los Angeles).—Few subjects have received more attention in medical literature than syphilology. The wide distribution of lues, with its varied and serious visceral manifestations must always make the disease a subject of intense study by all physicians, both in general and special practice. Because ocular syphilis, if improperly treated may lead to blindness, with all its sorrows, the proper treatment of luetic eye involvements is very important. As stated by the author, the present treatment of syphilis is comparatively recent, dating particularly from the discovery of the organism at fault, the introduction of the Wassermann test and the therapeutic use of the newer arsenicals and the bismuth preparations.

The reports in the literature of unfortunate experiences (with atoxyl as a cause of optic atrophy) naturally led to a prejudice to Ehrlich's 606 and the other arsenicals that followed when used in the treatment of ocular syphilis, which even today exists here and there. Clinical and statistical evidence, however, go to show more and more that the arsphenamins should not only be used in ophthalmologic practice, but that in luetic uveitis and interstitial keratitis they should be resorted to early, and continued after the acute ocular symptoms have subsided, in order to prevent avoidable relapses. The use of the bismuth and mercury preparations as adjuncts is nearly always in order, the choice of preparations and their use in relation to the arsphenamins and other therapy being left largely in the hands of the syphilologist, with whom, as Doctor Barkan has stated, the ophthalmologist should be in close touch when patients suffering from severe ocular manifestations of lues are under joint care. The author has called attention to the happier results with the arsenical and other therapy, instituted and developed in the last twenty-five years, and we can only emphasize the importance of what he has told us; for not to proceed along the lines outlined by him leads only to deplorable end-results, which to the patients who become blind or near blind, are little less than tragedies.

TUMORS ON THE SPINAL CORD: THEIR DIAGNOSIS*

AN ANALYSIS OF FIFTY-NINE CASES

By O. W. Jones, Jr., M.D.
and
Howard C. Naffziger, M.D.
San Francisco

Discussion *by Carl W. Rand, M.D., Los Angeles; Cyril B. Courville, M.D., Los Angeles.*

THE object of this paper is to present the outstanding clinical features noted in a study of the last fifty-nine cases of tumor of the spinal cord seen at the University of California Hospital.

The first successful removal of a tumor of the spinal cord was accomplished by Sir Victor Horsley in 1887. Since that time our clinical knowledge of the subject has broadened, and many diagnostic aids have been established, the most valuable of which are the spinal puncture (simplified and perfected by Quincke in 1891) and its adaptation by Queckenstedt, in 1916, to the study of the hydrodynamics of the spinal fluid. Of these the Queckenstedt test is the more important. Its application permits recognition of partial or complete obstruction in the spinal fluid pathways.

Froin, in 1903, associated xanthochromia and coagulation (with or without an increase in the cell count) with a mechanical obstruction to the spinal fluid pathways. Seven years later, however, Nonne demonstrated that in such lesions an increase in the amount of globulin may be the only alteration.

The cisternal puncture (Ayer, 1920), and the combined cisternal and lumbar punctures offer a method of visualizing the altered hydraulics, and permit chemical and physical studies of the fluid removed from above and below the lesion. In 1923, Cushing and Ayer reported xanthochromia, as well as alterations in the amount of protein, both above and below tumors of the cauda equina. This finding deserves special mention because it is usually believed that xanthochromia occurs only below the level of the tumor.

Roentgenographic studies frequently demonstrate significant alterations in the vertebrae, such as narrowing of the pedicles, enlargement of the bony spinal canal or intervertebral foramen.

Lipiodol as a *localizing agent* (1922) has proved to be of great advantage in certain cases.

In 1931 we noted that bilateral compression of the jugular and other cervical veins enabled us to differentiate between radicular pain produced by gross intraspinal, space-consuming lesions, and extraspinal pain of radicular type.

In the differential diagnosis of tumors of the spinal cord it may be necessary to employ one or all of the diagnostic aids mentioned above.

AUTHORS' STUDY OF RECENT CASES

In our study of the last fifty-nine cases of tumor of the spinal cord and cauda equina at the University of California Hospital, we noted certain clinical peculiarities and characteristics associated with the various pathologic types of tumor. It is the object of this paper to present certain outstanding clinical features of the various types of tumor, according to location and pathologic classification.

The early diagnosis of tumors of the central nervous system is of utmost importance. Little can be accomplished by the surgical removal of a benign tumor if permanent damage to the cord has already occurred. In the group of patients with benign encapsulated tumors, 79.5 per cent received an excellent result. The average duration of partial or complete compression of the spinal cord was five and one-half months. Of the 20.5 per cent in whom the results were not satisfactory, the average duration of complete or almost complete loss of motor and sensory function was two years and four months.

Tumors arising from the spinal cord, meninges, nerve roots, and dura give early evidence of their presence. In our series, regardless of the type or location of the tumor, *pain* was the most common and usually the initial symptom. It often was present for a number of years before neurologic signs appeared. The pain often simulated that of other disorders, and the patients complained of rheumatism, neuritis, sciatica, lumbago, sacro-iliac strain, and abdominal symptoms. In the early stages the pain was invariably localized. In most instances it later developed into a combination of localized and radiating pain. When radiating pain appeared early it was unilateral, but eventually became bilateral late in the course of the disease.

Sensory alteration, motor weakness or disturbances of the sphincters were unusual as initial symptoms. In all cases the symptoms and signs could be explained on the basis of a single, progressive, space-consuming lesion.

The pathologic type and clinical peculiarities of the tumors in the series are of great interest.

HOUR-GLASS TUMORS

The first group is composed of the so-called hour-glass type of tumor. These tumors have an intraspinal portion connected by a small neck with an extraspinal enlargement. In our cases the connection occurred most frequently through an intervertebral foramen, but occasionally through an interlaminal space. It is generally accepted that hour-glass tumors are rare, yet there were fifteen such cases in this series.

The most important, single, subjective complaint in this group was localized pain, the duration of which varied from two weeks in one case to ten years in another. No pain was present in four cases. In general, the neurologic signs appeared relatively late and were characteristic of compression of the spinal cord.

Palpation of the extraspinal portion of the tumor was possible in the cervical region, and occasionally in the thoracic and lumbar regions. Roentgenograms of the spine proved extremely valuable. In addition to anteroposterior and lat-

Read before the Neuropsychiatry Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13 to 16, 1935.

eral exposures, special views should be taken to show the intervertebral foramina. Enlargement of the latter structures frequently was demonstrated as well as erosion of transverse processes, laminae or dorsal surfaces of the bodies of the vertebrae, or a shadow cast by the extraspinal portion of the tumor itself.

In the fifteen cases the commonest pathologic types were neurofibroma, dural endothelioma, and hemangio-endothelioma. There was one osteochrondroma.

A preoperative diagnosis of this peculiar method of growth is important. In the absence of positive neurologic findings, a diagnosis of intrathoracic tumor has been made, and the intrathoracic portion of an hour-glass tumor removed without appreciating its character. Such mistakes have resulted in hydrothorax from a tearing of the dura with the escape of clear cerebrospinal fluid. The majority of hour-glass tumors are slow-growing and many can be enucleated.

INTRAMEDULLARY AND EXTRAMEDULLARY EXTRADURAL TUMORS

The intramedullary tumors in the proved cases were gliomas. In each instance they were very extensive and demonstrated the characteristic infiltrating properties, making complete surgical removal impossible, although large portions sometimes were removed with improvement. Pain of the same type as that found in other cases of tumor was the initial symptom. The average duration of pain was a year and a half, but in one case pain was present for six years. In one case laparotomy had been performed because of the severity of the referred pain.

The differential diagnosis between intramedullary tumors and extramedullary intradural tumors is difficult as a rule. In our cases, however, one differential point proved to be of value.

In the *extramedullary* tumors there was usually a clear-cut history of gradually increasing compression of the spinal cord. In these cases the sensory level was almost always sharply demarcated, and tended to be more pronounced in the distal part of the lower extremities than in the higher segments corresponding to the level of the lesion.

In the *intramedullary* tumors the reverse was true—that is, the maximum sensory loss corresponded to the segments of the cord immediately involved, while the sensory alteration in the distal parts of the extremities was not so marked. In addition, in an intramedullary growth, the sensory findings tended to fade off above the level of the tumor in a more or less indefinite fashion.

TUMORS OF THE CONUS MEDULLARIS

Involvement of the conus medullaris by either an intramedullary or an extramedullary tumor led, in all instances, to early involvement of the sphincters and varying degrees of impotence.

TUMORS OF THE CAUDA EQUINA

In this study, tumors of the cauda equina formed the most interesting but the most difficult diagnostic problems. Many of the old-established diagnostic principles were further emphasized, and new diagnostic points were revealed.

The majority of the primary tumors of the cauda equina are slow-growing and usually benign. Because the cauda equina is made up entirely of nerve filaments, the first symptom resulting from compression of the nerve roots is *pain,* which may be constant or intermittent, dull or knife-like. It may remain localized and is invariably present for many years before motor or sensory disturbances become evident. The initial onset of pain is commonly associated with a mild form of trauma or back strain. Its distribution and character may be such as to simulate lumbosacral or sacro-iliac disease. It frequently is aggravated by coughing, straining, or exertion. The pain is likely to come on at night, some hours after retiring. It is relieved by standing up and walking about, and the patient soon learns that he can be relatively free from pain if he sleeps in the sitting position.

Of the fourteen tumors occurring in the region of the cauda equina, in this series, four pathologic types deserve mention: (1) neurofibromata; (2) dislocated nucleus pulposus (chordoma); (3) epidermoids; and (4) large, soft, dural endotheliomata.

1. *Neurofibromata.* — These are slow-growing. Because these tumors arise from the sheath of a nerve root, radiating pain is the first and predominating symptom. In our patients such pain was present for as long as seven or eight years before the appearance of positive neurologic signs. Initially, it was unilateral and finally bilateral. In each instance, bilateral compression of the jugular veins reproduced the characteristic pain.

2. *Dislocated Nucleus Pulposus or Intervertebral Cartilage.* — That portion of the notocord which remains in the center of each intervertebral fibrocartilage is known as the nucleus pulposus. It is a highly elastic structure. If severe force is applied to the spine, a tear of the annulus fibrosus or a break in the intervertebral cartilage may result in a herniation of the nucleus, which may take place in one of several directions. Dorsal herniation frequently results in compression of the nerve structures. In some instances, portions of the hyaline cartilage of the disk may become separated and dislocate dorsally producing comparable effects. In either instance, repeated mild or severe trauma causes further dislocation with increased pressure on the adjacent nerve tissue.

In this series there were four cases of dislocated nucleus pulposus. The symptoms were intermittently progressive, and remissions were not uncommon. Pain, the initial symptom in each case, was of the local type and in one case was present for thirteen years before the appearance of neurologic signs, though the average duration was five and one-half years. In every case the pain simulated mild arthritis, sciatica, lumbosacral or sacro-iliac strain. In three cases lipiodol localized the level of the lesion and cast the characteristic x-ray shadow of dorsal dislocation.

3. *Intradural-Epidermoid and Dermoid Tumors.* Tumors of this type are rare. In the literature they are classified as teratoma, teratoid and epi-

dermoid cysts, cholesteatoma and dermoid tumors, according to the number of germ layers present. They may occur at any point along the midline from the cephalic to the caudal extremity. Those in our series involved the cauda equina. The complex embryologic development of the rectum, anus, and caudal end of the spinal cord and its appendages, lends itself to the development of such tumors in association with bony anomalies; such association was found in two of our cases.

The delayed appearance of neurologic signs is best explained by the slow-growing character and soft content of these tumors. In one of the four cases pain was the only symptom over a period of forty-two years. The tumor measured 15 by 4 centimeters. In each instance the tumor was composed of soft, cheesy material, cholesterol crystals, and hair, the greater portion of which was encapsulated.

The reproduction of typical pain on bilateral jugular compression was present in three of the four cases. In two instances severe pain was reproduced on attempted spinal puncture. The explanation of this was found at operation. The dural sac, being completely filled by the tumor, had compressed the nerve roots against the dura so that they were directly stimulated by the needle. The production of severe pain on spinal puncture is, therefore, suggestive of a tumor which prevents dislocation of the nerve roots.

Because of the slow growth of these large, so-called giant tumors of the cauda equina, definite bony alterations can be demonstrated by x-ray examination. These alterations consist in narrowing of the pedicles, thinning of the laminae, and erosion of the posterior surfaces of the bodies of the vertebrae with resultant enlargement of the bony spinal canal.

4. *Dural Endotheliomata.*—Many of these tumors grow to enormous size and, because they are soft in consistency, produce pain for many years before the appearance of positive neurologic signs. In one instance a tumor of this type measured, before removal, 10 by 5 centimeters. In this case there were no positive neurologic findings; pain was the only complaint. The clinical and x-ray findings in these cases were comparable to those of the large dermoid tumors.

COMMENT

It is evident from a study of the cases in this series that *pain* as the initial symptom is most common. It may be localized or radiating in character. In patients in whom pain persists regardless of the treatment employed, the possibility of tumor of the spinal cord must be considered.

Early diagnosis is essential. End-results bear a direct relation to the duration and degree of motor and sensory impairment, as well as the pathologic type of the tumor.

For use in a differential diagnosis, various diagnostic aids are of value. The simplest of these is that of compression of the jugular and cervical veins. This test was applied in the last twenty-six cases in this series, and gave a positive reaction in 50 per cent. The frequency with which tumors of the conus medullaris and cauda equina simulate orthopedic disorders warrants the recommendation that this test be employed routinely in orthopedic examinations in which localized or radicular pain is present.

The test is performed readily in an office and should be carried out with the patient in both the sitting and recumbent positions. The patient is placed in a comfortable position and, when free from pain, compression of the cervical veins is made as in the familiar Queckenstedt test. As the intracranial and intraspinal pressure above the level of the block is raised, the characteristic pain may be produced if the tumor is capable of being displaced sufficiently to cause traction on or irritation of a nerve root. Although most commonly the pain is reproduced by compression of the jugular and other cervical veins, in certain instances (depending presumably on the direction in which the tumor dislocates most readily) such pain may be experienced only on sudden release of the jugular compression.

Though radicular pain is commoner in cases of tumor of the cauda equina, the value of the test is by no means limited to tumors of this region, but has proved of differential value in lesions of various pathologic types involving the cervical and thoracic portions of the spinal cord.

University of California Hospital.

DISCUSSION

Carl W. Rand, M. D. (523 West Sixth Street, Los Angeles).—I have enjoyed hearing the résumé by Doctors Naffziger and Jones of their experiences with spinal cord tumors at the University of California Medical School.

It happens that one of their cases, an hour-glass tumor of the neurofibroma type, subsequently came under my observation. The original tumor was operated upon by Dr. Howard Fleming in March, 1932. By July, 1934, there were signs of recurrence of the growth, and the patient was once more operated on September 4, 1934. The pathologic report again was a neurofibroma, and comparison with the original tumor slides showed the tissue to be identical. The tumor could only be partially removed. His remission lasted until December, 1934, when, for the third time, he was operated upon. Large portions of the tumor were again removed. The pathologic report did not indicate beginning malignancy. Another period of improvement lasted for about eight months. Upon return of paraplegia he was operated for the fourth time on August 8, 1935. At this sitting, a tumor much larger than before was found. It was removed as well as could be. The pathologist reported this material much more cellular than that removed on previous occasions, and stated "the tumor should no longer be considered neurofibroma, but neurofibrosarcoma." While patients harboring tumors of this type are usually cured by the first operative removal, this case, observed for approximately three years, shows that malignant changes may occasionally occur.

⁂

Cyril B. Courville, M. D. (312 North Boyle Avenue, Los Angeles).—This survey presents within a brief scope the essentials of the pathology and symptomatology of a group of the most hopeful surgical lesions of the central nervous system. It is indeed a tragedy of major rank in our day to permit a benign, encapsulated and enucleable dural tumor to pursue an uninterrupted course to the point of advanced and irrecoverable damage to the spinal cord. It is a tribute to the intelligence and alertness of the general practitioner that this sort of episode is now of rare occurrence.

The opportunity to study the records of fifty-nine cases of intraspinal tumor is not given to all of us, and the authors have discharged well their obligation to the profession by reporting their observations. So large a percentage of hour-glass tumors is somewhat surprising even to some of us who perhaps should be better informed. If these figures are representative, it behooves the roentgenologist to pay more attention to the relative size of intervertebral foramina in the suspected region. That we do not scrutinize critically enough the radiographs of the spine in suspected intraspinal tumors has been impressed upon me in recent years. Enlargements of the foramina, erosion of the pedicles or the lamina, and calcification or ossification within the tumor, are all too often overlooked.

Three clinical observations have proved to be helpful in my experience in the diagnosis of intraspinal tumors. The first one is now quite widely recognized, *i. e.*, the slowly and progressively ascending sensory level which may mislead the observer as to the true location of the tumor until late in the course of the condition. A second symptom, occurring typically in the ependymogliomas arising in the cervical segments of the cord, is the impairment of thermal sense in the upper extremities which stimulates the findings in syringomyelia. A third observation of interest concerns tumors of the roots of the spinal nerves with pain as the outstanding symptom. This pain is often radicular in character, occurring in spasms which become more and more frequent and severe. If sensation is tested in the area affected by the pain during the episode or immediately afterward, a typical radicular area of hypesthesia may be outlined. The finding of a xanthochromic fluid and evidences of block on the Queckenstedt test usually helps in clearing up any doubtful situations.

PITUITARY GROWTH FACTOR*

SOME CLINICAL CONSIDERATIONS

By E. Kost Shelton, M.D.
Santa Barbara

Discussion *by H. Lisser, M. D., San Francisco; Lyman A. Cavanaugh, M. D., Santa Barbara.*

THE growth factor was the first secretory influence to be suspected and verified in the pituitary gland. In 1885, Pierre Marie described, "a peculiar, noncongenital hypertrophy of the upper, lower and cephalic extremities," which he termed acromegaly. Two years later Minkowski suggested the rôle of the pituitary in this process. Marie, who was soon won to this point of view, felt that the disorder must be due to underfunction of the organ, if it was not a problem of intoxication rather than of aberrant secretion. His conception was natural since, at autopsy, most of the cases recorded proved to have destructive tumors in this area. While Sir Arthur Keith was first to recognize an enlargement of the sella turcica in relation to gigantism, he held much the same view as Marie regarding the processes involved. Massolongo (1892) not only argued that acromegaly and gigantism were one and the same disorder at different periods of life, but, through careful histological studies, suggested that both were the result of excessive, rather than of diminished, secretion. By the turn of the century, Hutchinson's findings of definite pituitary hyperplasia in forty-four out of forty-eight autopsied acromegalies left little doubt on this point.

EARLY ATTEMPTS AT HYPOPHYSECTOMY

As Futcher tells us, "further knowledge of the pituitary mechanism could only be gained through experiments on the gland and the latter's fortified position in the center of the head thwarted many investigators." Early attempts at hypophysectomy, by Paulesco and others, in mature animals, had been almost invariably fatal. Cushing, whose reported work goes back to 1909, found that while extirpation of the posterior lobe alone did not produce death, total ablation ended fatally, although he felt that the fatal issue could be postponed by glandular implants. His partially hypophysectomized animals, which survived, failed to grow, and became obese and sexually dystrophic. So that even as late as 1910, most, if not all, observers felt that the gland was immediately essential to life. In that year, however, Bernard Ashner showed that immature puppies not only tolerated hypophysectomy well, but that they remained dwarfed and sexually immature. This finding was a great stimulus to experimental surgery, although the operative technique remained difficult and the mortality rate high.

CHOICE OF THE RAT AS AN EXPERIMENTAL ANIMAL

B. M. Allen and P. E. Smith, working independently, were among the first to show that removal of the buccal anlage in the tadpole resulted in cessation of growth and failure of metamorphosis into the frog. By the simple expedient of grafting bits of pituitary under the skin of the tadpole, it was then demonstrated that both growth and development were resumed. The choice of the rat as an experimental animal by Evans and Long (1921) proved a happy one. By intraperitoneal administration of fresh anterior lobe substance into numerous animals, these observers reported a consistent effect upon growth and upon the estrus cycle. It was not until Smith's discovery (1926), however, that the rat could be easily hypophysectomized, opening the way for both withdrawal and substitution experiments, that the subject received its greatest impetus. From this time on, pituitary research spread in many directions, but the process of growth continued to occupy a number of able observers. Dandy and Reichert showed that hypophysectomy can be accomplished in the dog by a new and comparatively safe operative technique. Reichert, using Evans' bovine extract intraperitoneally, was able to bring an hypophysectomized animal to a size that exceeded its normal litter mate control. Evans and his associates, using their own extract, and Putnam, Benedict and Teel, using a similar but entirely independent preparation, produced what was comparable to canine acromegaly.

CUSHING'S EFFORT TO REHABILITATE THREE PITUITARY DWARFS

During the summer of 1929, Cushing attempted the rehabilitation of three pituitary dwarfs ranging in ages from nineteen to thirty, with indifferent success. He later discovered (by testing on rats) that most of the growth promoting principle in the preparation he was using had been destroyed.

* From the department of medicine, University of Southern California.

Read before the General Medicine Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

In 1932 the same observer administered a more potent preparation, for a period of one hundred and ten days, to a former operative (hypophysectomized) patient, who had failed to mature or to keep up in the normal growth increment. While, as one would expect, there was little stimulation of growth in such a short period, subjective improvement was apparent. In 1930, Engelbach, Shelton, Cavanaugh and Evans began the treatment of a dwarfed child by the intragluteal administration of an alkaline extract of the bovine adenohypophysis, which had been demonstrated active by intraperitoneal injection in dogs and rats. Stimulation of growth in the human was proved. While the observation was perhaps of scientific value, its clinical significance remained in doubt. Since this time the last three observers, employing the same preparation (herein known as G. H. fraction A),* and Shelton and Cavanaugh, using a similar but entirely independent extract prepared by a modification of the Van Dyke and Wallen-Lawrence technique (herein known as G. H. fraction B),† have attempted to evaluate the use of such extracts in clinical medicine.

PROBLEMS ARISING IN A CRITICAL ANALYSIS OF THE CLINICAL ASPECTS

It appeared that a critical analysis of the clinical aspect of this subject was the best approach. For this reason three questions were propounded: (1) Would a potent hypophyseal growth promoting hormone be of value in clinical medicine? (2) If so, are the preparations under discussion sufficiently active to be practical? (3) Are these preparations otherwise physiologically innocuous, or would their indiscriminate use be attended by danger?

In an attempt to answer these questions, the following clinical material has been employed: One hypophysectomized child, four outstanding dwarfs ranging in ages from eight to twenty-eight years, six dwarfish individuals, or those several inches under the low borders of normal height, two barely short of the low borders of normal, one adult with fugitive acromegaly, two of a modified form of pituitary cachexia and several obscure endocrinopathies. The preparations, because they contain a prolan synergist (or activator), have also been used, in conjunction with pregnancy urine prolan, in a limited number of children suffering from adiposogenital dystrophy, with whom, in this paper, we are not concerned. In the conduct of the research every effort has been made to control the observation. However, it is one thing to operate upon a dog or a rat, or, to overwhelm their economies with myriad glandular extracts and read the results a few weeks later, and quite another to make controlled and convincing observations in an ailing human. No thyroid, vitamins, minerals or other preparations have been employed over long periods of observation although they have sometimes been used during intervals as therapeutic controls. Engelbach and Schaefer report on the stimulation of growth in children with retarded bone development by means of the administration of 2 cubic centimeters of an anterior pituitary growth fraction, three times a week. Desiccated thyroid was given concomitantly. It was stated in the protocol, that thyroid alone was administered for a period of from two to six months, without a resultant increase in height, before the pituitary fraction was added. It is interesting to note, however, that the Engelbach-Schaefer dwarfs with the greatest degree of bone retardation grew the most. One wonders what, if anything, the small doses of the pituitary preparation had to do with the ultimate growth. It has been shown that retarded bone development, is, if not actually pathognomonic, at least a consistent finding in long standing hypothyroidism of childhood. The more retarded the osseous development, the more rapid the somatic unfolding and the concomitant increase in height following thyroid administration. A number of our hypothyroid dwarfs have gained as much as five inches a year on thyroid substitution alone. In borderline cases (those with only a moderate degree of carpal retardation), the growth spurt, as in the normal, is frequently delayed for several months. Consideration of such factors may invalidate the negative control period with thyroid medication alone, and make difficult the interpretation of subsequent findings. This does not argue that some, or perhaps all of our dwarfs, do not need thyroid, high vitamins or minerals as adjuncts to their treatment. A number may well profit thereby. The pituitary thyroid relationship is well established and P. E. Smith has recently shown that hypophysectomized rats develop more rapidly on both thyroid and pituitary substitution than upon pituitary substitution alone. It means that we have attempted to evaluate the growth promoting fraction of the hypophysis in a manner most conducive to a scientific conclusion. After having arrived at such a conclusion, one should be better able to evaluate its degree of usefulness in enhancing the other known growth promoting factors.

THE PROBLEM OF DOSAGE

The dose has been and remains a problem. The minimum growth stimulating dose of both preparations (G. H. fractions A and B) when given intraperitoneally to a rat weighing approximately 300 grams is from 0.25 to 0.5 cubic centimeter daily, for from fifteen to twenty days. This would be comparable to from 15 to 30 cubic centimeters intraperitoneally for a child weighing forty pounds. All of our injections have been given intramuscularly and theoretically at least, the minimum effective dose when given to such a child, in such a manner, would be even larger. While we have administered as much as 13 cubic centimeters daily for a short period, our average dose has approximated 5 cubic centimeters daily intragluteally six days a week, except in adult patients suffering from so-called pituitary cachexia, where the growth stimulating property was not desired. If, as the Engelbach-Schaefer protocol would infer, stimulation of growth actually resulted from

† The material for this study was supplied through the research department of E. R. Squibb and Sons.

2 cubic centimeters of the pituitary fraction, when given three times a week, then one of four things must be apparent, namely, either there is a remarkable species difference in the growth response, or their preparation is more potent than those we have employed, or we have produced an antigrowth mechanism by too large a dose, or there is a more remarkable synergistic action between these preparations and the thyroid hormones than we have previously considered. One would not care to arrive at any of these conclusions without ample verification of their findings. The experiences of Lisser, who employed the same preparation as the previously mentioned observers, are similar to ours. In a series of carefully controlled observations, although admitting stimulation of growth, he has not been able to convince himself of any miraculous growth promoting principle in the product. He also agrees with us that the patients ultimately appear to become refractory, about more of which will be said anon. This is an outstanding example of the difficulties attending such a research.

REPORT OF CASES

While much of our material continues under observation, we feel that enough has been learned to warrant reporting. In order that the reader may share in the ground work, a few case reports are given in brief.*

Case 1.—P. P., aged twenty-five years, had been in perfect health until 1931. Following an acute cerebral episode, diagnosed as some form of meningitis, there developed a progressive asthenia, anorexia and loss of weight (from 189 pounds to 130 pounds). Roentgen studies of skull and extremities revealed changes characteristic of acromegaly. On the contrary, his complaints, taken with evidence of a high glucose tolerance, increased insulin sensitivity, low oxygen consumption (minus 40 per cent), hypotension (105/80) and the presence of a calcified shadow within the sella, pointed to pituitary deficiency. It was felt this condition was probably engrafted on a previous early and insidious acromegalic state. It was seen that neither thyroid medication, adrenal substitution by mouth, nor dietary measures were capable of arresting weight loss, or diminishing the asthenia. The intramuscular administration of an alkaline extract of the anterior pituitary (fraction A) led at once to weight gain and subjective improvement. The hypometabolism and hypotension remained unaltered. This observation was repeated at interrupted intervals over a period of twenty months (fractions A and B) with consistent results. The patient was partially rehabilitated with pituitary substitution, and continues to maintain at a low level of normalcy.

To avoid repetition, the negative findings in the following patients will be considered en masse. In no instance was either parent under sixty-one inches in height. There is no history of dwarfism in any family. Physical examination revealed nothing abnormal in the heart, lungs, or abdomen of any of the patients. The urine was normal and a negative Wassermann was found in all. The blood pictures were consistently normal.

Case 2.—B. J., a male, aged seventeen years one month, of Anglo-Saxon parentage, consulted us September 20, 1933, complaining of understature. Height 63.8 inches, weight 111 pounds. The previous annual increment was estimated at approximately 1 inch. Physical examination revealed nothing abnormal except retarded growth and development. Roentgen studies revealed a normal sella and open epiphyses. Treatment: Alkaline extract bovine anterior hypophysis (G. H. fraction A) was given five days weekly intragluteally. Maximum dose 5 cubic centimeters. Treatment continuous for eleven months. Actual increment 1.7 inches. The estimated increment was 1 inch. The average normal increment for the same age is 1.1 inches. Weight gain was 6.1 pounds. At the end of the following year without treatment, his height was 65.8 inches and the weight was 116.8 pounds (no gain).

* * *

Case 3.—L. A., a male, aged seventeen years nine months, of Italian parentage, consulted us June 26, 1934, complaining of understature. Height 57.9 inches, weight 83.2 pounds. The previous annual increment unknown. Physical examination revealed nothing abnormal except retarded growth and genital development. Roentgen studies revealed a normal sella and almost completely closed epiphyses. B. M. R. estimations averaged minus 22 per cent. Treatment: Alkaline extract bovine anterior hypophysis (fraction B) given intragluteally three days a week. Maximum dose 5 cubic centimeters. Desiccated thyroid with high iodin content grains one to one and one-half daily. Treatment continuous for six months. Actual increment 0.4 inch (within limits of error). Weight gain 10 pounds.

* * *

Case 4.—W. M., a male, aged twenty-seven years nine months, of Anglo-Saxon parentage, height 53 inches, weight 71.3 pounds. No secondary sex characters. Genital hypoplasia. The annual increment for the previous four years was 0.5 inches. B. M. R. estimations averaged minus 22 per cent. Carbohydrate tolerance was high. Roentgen studies revealed a microsella and open epiphyses. Treatment: Desiccated thyroid grains one-half daily for three and one-half months. There was no appreciable increase in height during this period. Weight loss 7 pounds. Thyroid was discontinued and the alkaline extract of the anterior lobe of the pituitary (fraction B) was given five days weekly. Maximum dose 5 cubic centimeters. Treatment continuous for twelve months. Actual increment 1.1 inches. The estimated increment for twelve months was 0.5 inch. Roentgen studies were made at the close of this period, and epiphyses were found to be open to the same degree as on original examination.

* * *

Case 5.—F. O., a male, aged eleven years five months, consulted us complaining of understature. Height 47 inches. Weight 51.8 pounds. The annual increment for the previous four years was 1.4 inches. Physical examination revealed nothing abnormal except retarded growth and development. B. M. R. estimations averaged plus 12 per cent. Roentgen studies revealed rudimentary anterior clinoids of the sella turcica and open epiphyses. This patient was used as a control and received no treatment for twenty-three months. The actual increment in twenty-three months was 3.2 inches. The estimated increment based on the average for the previous four years was 2.68 inches. The average normal increment for this age is 3.7 inches. The weight gain was 12.8 pounds. The patient was then given the alkaline extract of the bovine anterior hypophysis (fraction A for six months, fraction B for fourteen months) intragluteally five days a week. Maximum dose 6 cubic centimeters. Treatment was continuous for twenty months. The actual increment was 5.4 inches. The estimated increment based on the previous average (while under observation but without treatment) was 2.8 inches. The average normal increment for that age is 2.83 inches. The weight gain was 19 pounds. The patient was then placed on desiccated thyroid with high iodin content, one-half grain daily for six months (without A. P. E.). The actual increment during this period was 1.3 inches. The estimated increment based on the rate during the control period was 0.85 inch. The average normal increment for this same period was 0.8 inch. The weight gain was 9.5 pounds. B. M. R. estimations at the close of this observation averaged minus 5.5 per cent.

---

* A preliminary report of six cases of dwarfism was published in the *American Journal Diseases of Children*, volume 47, pages 719-735, April, 1934. While these children continue to be among our most informative observations (as regards the effect of G. H. fractions A and B on growth), it is felt their protocols continue to belong to this *Journal* and cannot be set down here.

COMMENT

From these and other observations we are forced to believe that there is a genuine need for a potent hypophyseal growth promoting hormone in clinical medicine. First, because of the myriad sufferers from understature who crave a semblance of normalcy. No one, not actively engaged in this type of endeavor, can appreciate the somatopsychic inferiorities with which many of these persons are afflicted. Fortunately, this is not always true of the actual dwarf who, for economic reasons, frequently finds it more profitable to be very small than merely a few inches under the low average normal. Secondly, while classic Simmond's Disease is rare, a form of borderline or modified pituitary cachexia is, perhaps, more common than many suspect, particularly the transitional or so-called burned out pituitary case.* When considering that acidophilic elements in the adenohypophysis must have an important place in the maintenance of the body economy long after the process of growth is completed, and that in spite of their protected position they are vulnerable to new growth, hemorrhage, infarcts, cysts, calcification, abscess formation, syphilis and other inflammatory processes, bony encroachment, defective development, metabolic disorders originating elsewhere and even functional disturbances of the vascular and nervous mechanism, this should not be surprising. Aside from these, there is need for a potent product in clinical research as in the therapeutic investigation of obscure bone, joint and muscular dystrophies, which may prove of pituitary origin.

ARE AVAILABLE PREPARATIONS OF PRACTICAL USE IN CLINICAL MEDICINE?

Are the preparations, now available, sufficiently active to be of practical use in clinical medicine? In common parlance, the answer is yes and no. Evidence has been presented to show how one case of so-called transitional acromegaly responded and continues to maintain on the growth fraction available. We have had encouraging results in others whom we have considered as having pituitary deficiency. The physiologic problem in classic Simmond's Disease is exceedingly complex. It is quite likely that the adrenotropic, thyrotropic, contra-insular and gonadotropic, if not other pituitary fractions and the hormones of other glands, are equally at fault. It appears, however, that physicians have been too prone to depend upon the classic picture for a diagnosis. Everything must have a beginning, and in metabolic or endocrin disorders they are often insidious and, therefore, masked. It may be argued that contamination of our product with some of the other active principles had more to do with the partial rehabilitation of the transitional acromegaly patient than the growth factor. To us, this would not appear to be true. While there was marked gain in weight and muscular strength in our patient, no change whatever was noted in blood pressure or oxygen consumption, and very little in the glucose tolerance. From this standpoint, then, the present preparations are apparently potent enough to save life or at least to prevent invalidism in selected cases. Neither of the preparations which we have used is sufficiently active, in growth promoting properties, to be practical in the rehabilitation of dwarfism. Neither do we feel that they would prove practical in the prevention of hypophyseal dwarfism, in which there is complete or nearly complete absence of the natural hypophyseal secretion. On the other hand, unless we have deceived ourselves, which is quite possible in such a research, we feel that either one of the preparations is of sufficient potency to be practical in the partial (perhaps total) rehabilitation of dwarfish or borderline individuals who, by consistently losing in the growth increment, would otherwise remain staturally immature. After all is said and done, therefore, we believe that while these preparations do not warrant enthusiasm regarding their growth promoting properties, they are better than none. A much more potent extract is to be desired if it is to find practical use in clinical medicine.

ARE AVAILABLE PREPARATIONS PHYSIOLOGICALLY INNOCUOUS?

Are these preparations otherwise physiologically innocuous, or would their indiscriminate use be attended by danger? The answer to this question is the most difficult of all. It is not the purpose of this paper to elaborate upon the various physiologic principles *suspected* of originating in the hypophysis. Suffice it to say that, with growth, gonadotropic, lactogenic, thyrotropic, adenotropic, parathyrotropic, contrainsular and lipoid influencing fractions to deal with in the adenohypophysis, to say nothing of pressor, oxytocic, pigment influencing and probably gastric influencing fractions in the pars intermedia and only three, or four recognizable type of cells to secrete them, the present physiologic status is, at best, confusing. While it is difficult, for one familiar with the cytology of the pituitary, to believe that each and every one of the principles or fractions mentioned is a chemically identifiable hormone, and not merely a physiologic phase of a few mechanisms, the growth hormone would appear to stand a good chance of ultimate recovery in the pure chemical state.

PROBLEMS ARISING IN TREATMENT OF PATIENTS WITH HYPOPITUITARISM

Most sufferers from hypopituitarism, or what we have taken to be hypopituitarism (since the diagnosis must remain unverified except in rare instances), show clinical and laboratory evidence of multiple physiologic deficiencies, *i. e.*, understature, cachexia, low oxygen consumption, low blood-pressure, high carbohydrate tolerance, genital hypoplasia, etc., either alone or in combination. Theoretically, therefore, a mixture of a number of physiologic principles for artificial administration should be ideal. On the other hand, one could never hope to balance these fractions in a test tube as they appear to be in the normal body economy. Biochemists have, for this reason, attempted to separate them into pure physiologic principles so that they might be reintroduced according to physiologic demand. Their efforts have been attended with only moderate success. While the preparations which we have employed are relatively free from such contaminating influence, they contain traces of the thyrotropic, sex complementary, contrainsular, and perhaps other fractions. Seibert and Smith, Lee, Teel and Gagnon, Thompson and others have shown, and we have verified,* that the thyrotropic hormone quickly raises the oxygen consumption and will subsequently depress it even to a degree not encountered at the start. Thyroid hyperplasia followed by thyroid atrophy has attended its use. Houssay, Evans and others have shown that some preparations are so insulin-antagonistic as to produce experimental diabetes, while the sex fractions, if given in excess, or over a prolonged period, may produce wholly undesired results. By careful and repeated tests on our patients over a period of four years, we have been unable to discover but few untoward physiologic reactions. That these reactions may be latent, however, we wish to point out a lowering of the carbohydrate utilization and the appearance of glycosuria in one of our dwarfs (whom we have had under treatment for four years) within the past few weeks. The general level of oxygen consumption is also moderately lower at present than at the beginning of the experiment. Otherwise, every person we have treated appears in the best of general health with the possible exception of those considered as suffering from pituitary cachexia, who remain only partially rehabilitated.

---

* Cushing and Bailey and others have pointed out that acromegalies and giants, who have early suffered from hyperpituitary conditions may and frequently do drift into hypopituitary states. Whether the pituitary adenoma actually burns out from excessive secretion (as an exhaustion state), or the secretory embarrassment is due to infarcation, calcification, hemorrhage, compression, or some other factor, is unknown. One such case is herein reported.

ANTIHORMONE THEORY OF COLLIP

Another disquieting note in the difficult composition of clinical research is the antihormone theory of Collip and his associates. What happens to the treated individuals after they have received the growth fraction for any length of time? Does one develop antihormones and destroy what little chance he may have for spontaneous recovery? From our findings we have not, so far, felt this to be true. There is definite evidence, however, that the response to the hormone is greater at first than subsequently. In the case of the twenty-eight-year-old dwarf, with open epiphyses, there was very little response from the beginning. This, of course, argues an antihormone or other antagonistic effect. If there is a true antihormone effect it must exert its influence in the normal, since all normal individuals are constantly bathed in hormones. The artificial administration of a natural product (free from contaminating proteins) should not embarrass the body economy when given in the proper dose and at the proper time. Therefore, so far as clinical medicine is concerned, it remains a matter for investigation and not one for panic. In final analysis, while from our experiences, the dangers of these preparations in clinical medicine would appear exaggerated, we must admit that their indiscriminate use, at the present time, would not be without an element of danger. A pure growth hormone without the contamination of other physiologic principles and a better understanding of the so-called antihormone influences are highly desirable.

SUMMARY AND CONCLUSIONS

After some years' experience with two preparations of the bovine adenohypophysis relatively high in growth promoting principles, an attempt is made to evaluate their clinical usefulness. In a critical analysis three questions were propounded: (1) Would a potent hypophyseal growth promoting hormone be of value in clinical medicine? (2) If so, are the preparations under discussion sufficiently active to be practical? (3) Are these preparations otherwise physiologically innocuous, or might their indiscriminate use be attended by danger?

While much of the clinical material continues under observation, it is felt enough has been learned to warrant a few conclusions, namely, a pure, potent, hypophyseal growth hormone would be a boon to medicine. The preparations under discussion are sufficiently active to stimulate growth (during the growth period), but not at a rate, sufficiently above normal, to rehabilitate the classic dwarf. They appear to have little effect, after the growth period, even when the epiphyses remain open. It is theoretically possible, but clinically impractical to prevent dwarfism, when the growth increment is 50 per cent or more deficient. It would appear that they are sufficiently active to keep the growth up to, or slightly in excess of the normal, in persons who are from 25 to 50 per cent deficient in the growth increment. They are also sufficiently active to produce a rapid gain in weight and increased muscular strength and to maintain, at a low level of normalcy, persons suffering from modified forms of pituitary cachexia resembling transitional acromegaly or Simmond's Disease. In final analysis, while the growth stimulating property of these preparations does not warrant enthusiasm, the preparations are clinically useful. Although few untoward effects have been discovered, in persons treated by these preparations, and the dangers incident to their use would appear exaggerated, their contamination with other active hypophyseal fractions, together with the possibility of producing antagonistic influences, would make their indiscriminate use, at this time, undesirable.*

24 West Micheltorena Street.

DISCUSSION

H. Lisser, M. D. (384 Post Street, San Francisco).—It is a pleasure to discuss this paper. Doctor Shelton is well aware that I would not hesitate to disagree with him if my opinions differed from his. It so happens that our experiences and interpretations regarding the clinical application of the pituitary growth factor coincide in almost every particular.

---

* Case No. 1 herein reported.

* Keyed references to this article will be given in the reprints.

When Evans, in 1923, announced his brilliant production of gigantism in the rat by intraperitoneal injections of an extract he had prepared from the bovine adenohypophysis, I looked forward with enthusiasm to utilizing such a preparation in human cases of hypophyseal infantilism. Although it is admitted that pituitary dwarfs are relatively uncommon (but by no means rare), milder instances of skeletal and genital retardation, due to anterior pituitary deficiency, are encountered frequently. It was, therefore, a great disappointment to wait in vain, year after year, for this pituitary growth stimulant. Meanwhile, occasional success was attained from the oral use of anterior pituitary powder, put up in salol-coated capsules and taken in fairly large doses over a period of two to three years, despite the fact that the oral administration of pituitary products, experimentally, was supposed to be ineffective.

At last, within the past two or three years, three pharmaceutical houses have prepared what purports to be a product containing the growth-stimulating principle of the anterior pituitary (not in pure form), and have provided me with a generous supply for clinical research, prior to placing these products on the market commercially. It is to be stated at once that these preparations have not, in a single instance, produced a spectacular growth comparable to that achieved over and over again by the simple administration of thyroid substance to myxedematous dwarfs. In the latter condition, an increase of height between six inches and a foot, in a single year, has been accomplished frequently. Theoretically, a similarly potent anterior pituitary growth hormone should stimulate an equal growth increment in cases of hypophyseal infantilism. To date, this has not been consummated. Furthermore, daily injections over months and years are somewhat inconvenient as compared with the simple oral administration of thyroid substance, particularly if doses of five cubic centimeters or more are necessary. In my experience, which covers at least thirty cases of retarded growth, interpreted as due to primary pituitary deficiency, we have never administered more than three cubic centimeters daily, and ordinarily have been content with one or two cubic centimeter doses.

Our results may be tersely summarized as follows: A minority have not responded at all; a minority have exceeded somewhat the normal rate of growth; the majority have been stimulated to grow at approximately the normal rate. With regard to the first group, I would utter a word of caution, namely, of routinely excluding the possibility of renal dwarfism. We have recently encountered two instances that readily could have been mistaken for pituitary infantilism; both had lowered basal rates and retarded bone age, but most certainly were not examples of childhood myxedema; investigation of their blood nonprotein nitrogen and phthalein output revealed them as instances of renal dwarfism; naturally one would not expect success in treating this condition with either thyroid or pituitary hormones. With regard to the majority group, who respond with a fairly normal growth rate: conceivably the criticism might be made that the growth obtained occurred naturally and should not be ascribed to the pituitary therapy. However, such an assumption would appear to be most unlikely in view of the abnormally slow growth prior to treatment.

Although it may be inferred from the above that growth-stimulating treatment by the pituitary extracts at present available is discouraging, I hasten to add emphatically that even a moderate amount of growth is eminently worth while, unless, of course, the individual wishes to commercialize his or her dwarfism on the stage or in the circus. The embarrassment and the inferiority complex usually acquired by these boys and girls, particularly as they pass through the ordinary years of adolescence, is most pathetic. It is, therefore, incumbent upon us to utilize what we have, and do the best we can.

Finally, a word regarding the latest bugaboo—"antihormones." With no intention to disparage the eventual importance that may come from recognition of antihormone production in the human economy, it is none the less premature and ill-advised, on the basis of our present information, to become panicky over the clinical use of endocrine preparations. It is peculiar, to say the least, that thyroid substance can and must be continued for life in severe cases of childhood or adult myxedema without the remotest evidence that it ever loses its efficacy. It is equally odd that insulin therapy can be continued indefinitely in diabetes without apparently the development of an antihormone frustrating its action. There is no evidence as yet that posterior pituitary extract administered day after day by injection, or as a snuff to victims of diabetes insipidus, forfeits its potency. However, it must be admitted that patients with severe chronic tetany gradually become immunized to prolonged treatment with parathyroid extract. Whether this represents an antihormone action or an acquired immunity to some protein constituent of the extract, is not settled. Meanwhile it is unfortunate that the pronouncement of antihormone possibilities should so quickly frighten the clinician into abstaining from clearly indicated endocrine therapy. Only lately the discusser was called in consultation by a distinguished clinician in the case of a pituitary dwarf to whom the growth hormone had not been administered for fear of interfering with natural growth by the production of an antihormone.

In conclusion, permit me to congratulate the author on his splendid presentation of his well-controlled clinical experiences. He has presented the facts clearly and interpreted them wisely.

*

Lyman A. Cavanaugh, M. D. (34 West Micheltorena Street, Santa Barbara).—I feel that Doctor Shelton's approach to this problem is highly commendable. In the conduct of such a clinical research, there are many pitfalls to be avoided. To give scientific credence to the conclusions, the subjects must be carefully controlled. This is particularly true during the preadolescent and adolescent periods. In a similar study designed to evaluate the growth-stimulating properties of an anterior pituitary extract, in which Doctor Shelton and I collaborated, we saw one of our control cases (without treatment and under close observation) suddenly start growing in excess of the average normal.

The element of measurement also constitutes a source of error. When using the most rigid wall standard with measurements taken at the same time of day by the same experienced observer, there is frequently a variation of from three- to five-tenths of an inch. The variation, when taken on the ordinary insecure scale standards at different hours of the day by different observers, must be much greater.

Doctor Shelton's point as regards the fallacy of giving thyroid extract concomitantly during the period of scientific observation, is also well taken. The practice of giving polyglandular treatment has always been a great hindrance to the elucidation of clinical endocrinology. One must thoroughly understand the specific effect, if any, of each fraction before combinations can be intelligently administered. The ultimate viewpoint as to what regimen is best for a given subject will come only in the light of this knowledge.

Doctor Riddle has recently expressed the belief that the growth-stimulating properties of the anterior pituitary are the result of a combination of factors such as the thyrotropic, adrenotropic and gonadotropic fractions, and are not due to a specific growth hormone. Even if this were true, it would not detract from the need for a growth-promoting principle. It should make us more cautious, however, in administration.

GUNSHOT WOUNDS OF THE ABDOMEN

By R. W. Binkley, M.D.
and
E. R. Cole, M.D.
Selma

Discussion *by George K. Rhodes, M.D., San Francisco; H. Glenn Bell, M.D., San Francisco; John Homer Woolsey, Woodland.*

GUNSHOT wounds of the abdomen have been with us as long as have guns.

In civil life they came as the result, principally, of dueling, and carried an eventual mortality close to 100 per cent.

During the Revolutionary War penetrating gunshot wounds of the abdomen carried a mortality in the neighborhood of 90 per cent, because it was not the custom to employ surgery. Then, as today, if death followed quickly it was due to hemorrhage, and if delayed it was usually the consequence of the resultant peritonitis. Surgery, when it was instituted, was done for the purpose of controlling hemorrhage, and not with the idea of closing perforations. Even so, it reduced the mortality some.

During the Spanish-American War some five cases were treated with the purpose in mind of repairing the intra-abdominal damage, and there resulted another lowering of the mortality. Not, however, until within the last twenty-five years has it become the accepted and established practice immediately to explore and repair all gunshot wounds of the abdomen. And with the advent of this custom the mortality has been decreased to approximately 60 per cent and, strangely enough, though we have accepted this method for twenty-five years, there has been little improvement in the mortality during that time.

To place all penetrating wounds of the abdomen into one class for the purpose of statistics is a mistake; for the amount of hemorrhage and the extent and location of visceral damage is so variable that they should be classified accordingly. For example, the size of the bullet and the course it takes is important, even though the same visceral organs be penetrated. Wounds from front to back carry a higher mortality than those from back to front, other factors being constant. Wounds through solid organs carry a lower mortality in general, unless a large vessel is opened and the hemorrhage profuse, than wounds of the digestive canal. Then the solid organ injured affects the mortality, for pancreas injuries are more serious than an equal injury to liver or spleen. The reasons for this are obvious: wounds which open the intestinal tract are more serious because of resultant bacterial contamination. Also the level at which the intestinal tract is opened affects greatly the mortality because of the infectious nature of the material spilled. It is for that reason that injuries of the stomach and small intestine carry a lower mortality than do injuries of the colon, this being aside from the difficulty in repairing the intestinal tract at its different levels.

The above factors influencing mortality are in no way subject to the surgeon's control, and their attendant mortality can only be affected or lowered by our consideration of other factors which influence the mortality.

The first and foremost factor within our control has to do with the time element. In the majority of cases in civil life the first thought of the injured or those about him is to seek medical aid; consequently, as little time as is possible is lost with the first step. The next step is the time consumed after notification before treatment is instituted, and then another step involving time is the length consumed in the procedure instituted. These factors are definitely laid at the surgeon's door. Prey and Foster of Denver have stressed these two points forcibly in their paper, and have outlined a procedure which is applicable in the larger institutions where internes and staff officers first see the patient. They emphasize the fact that while the interne is waiting for the consultant, he should have the operating room made ready, intravenous started, blood grouped, and donors located. The time gained by such a procedure saves, no doubt, lives.

The surgeon who does not have those facilities should himself think along those lines, and as a result, as soon as he sees a patient with a gunshot wound of the abdomen, he will, while making the examination, have all preparation set in motion for the surgical procedure at the earliest possible moment. Of course, some surgical judgment must be exercised in the case of the patient in shock, but oftentimes it is impossible to say if the shock is traumatic or from hemorrhage. In either case intravenous glucose can be started immediately, before one is prepared for transfusion or operation, and it is better to go in on the case of traumatic shock than to stay out in the case of hemorrhage. I have twice seen this inability to determine the nature of the shock in cases of ruptured spleens with hemorrhage, and once in hemorrhage from a pelvic artery, and waiting to see, cost the life of one of the patients. If it is hemorrhage, to run fluids into the circulation is, obviously, not sufficient unless we stop the leak.

Then, too, in considering the abdominal cavity we must not forget that it extends farther upward than the rib margin and farther down than the pelvic brim, and any penetrating wound from its topmost border to its very floor must be considered as having injured some part of the intestinal tract, and the abdominal cavity must be regarded as potentially infected and the seat of future peritonitis if untreated.

For these reasons, in either case, to combat the early deaths from hemorrhage which constitute the larger group, and the later deaths from peritonitis the smaller group, it is essential to adopt the policy as expressed by Urban Maes: "Look to see, don't wait to see"; for to wait may be to lose the patient's best chances. During the World War to routinely operate upon these patients gave a lower mortality than waiting; for to wait until symptoms develop is to wait too long. Doctors Eliason and McLaughlin say, "No one with operating facilities today is justified in postponing these cases one hour. A penetrating missile will almost certainly injure vessels or a hollow viscus; the one causing hemorrhage, the other contamination and subsequent peritonitis. A surgeon has no right to hope that neither has happened. Immediate operation after the patient is deshocked is the safest procedure."

The following cases illustrate some of the above points of what not to do as well as what to do.

REPORT OF CASES

Case 1.—Boy, seven years old, threw rifle cartridge into stove and was shot in the abdomen, just above and to the left of the umbilicus. The patient was seen within one hour and immediate operation advised. The parents refused, on religious grounds. The child went through the usual course of a peritonitis and died on the eleventh day.

Comment.—This was a case of standing by and waiting for the inevitable.

* * *

Case 2.—Man, age 52, was shot in the right lower quadrant with shotgun while hunting. Seen about one and one-half hours after the accident and given hypodermic of one-half grain of morphin for pain, and transported by ambulance to the hospital. Telephoned ahead to have operating room and intravenous ready, and consultants waiting. Arrived at hospital one and one-quarter hours later. The patient was then comfortable from his morphin, had a pulse of 98, subnormal temperature, and blood pressure was 110/80. Examination of abdomen showed numerous separate bird-shot wounds over right lower quadrant especially, but extending from rib cage down onto thigh and over beyond midline. Catheterization showed no blood in the urine, suggesting that the bladder had not been penetrated. (The patient had voided just before the accident and bladder was contracted.) A consultation of four surgeons was held, and it was decided to wait for further developments, in spite of the fact that the operating room was in readiness. Within eight hours the pulse was 112, and in seventeen hours it was 124; but still the operation was postponed. The patient ran the usual course of a progressive peritonitis, with temperature, pulse, distention, and vomiting until the fifth day, when it was agreed he should have the advantage of an exploratory laparotomy. This was done under general anesthesia, and it was found that the abdominal cavity was the seat of a generalized peritonitis and the small intestine loops of the right side were riddled with small, leaking holes. A resection of the involved gut was hurriedly done, but the patient expired two days later, seven days following the accident.

Comment.—The patient was deprived of his only chance to live by not operating immediately. Stereoscopic x-rays would have shown that the shot had entered the abdominal cavity, but such was not available at the time. Bird-shot wounds of the stomach and intestine cause surprisingly little leakage in the first few hours. They are practically closed by the muscle layers until distention begins to develop. I saw one man opened four hours after being shot with bird shot, and though he had holes into the stomach, transverse colon, and loops of the small bowel, there was practically no leakage. Early exploration, under local anesthesia if necessary, until one is sure of contamination or lack of it, will save many of these.

* * *

Case 3.—Police officer, age 39, while on duty was shot with a .22-caliber long rifle in the right upper abdomen. He was taken immediately to the hospital, where he was seen by two physicians. The patient was not greatly shocked, and owing to location of the bullet hole and the position in which he was standing when shot, it was thought that the bullet was too high to pass through the intestines and had penetrated the liver instead. The bullet did not emerge through the back, so the exact direction could not be determined. Two other doctors saw the patient within the next ten hours, and it was decided to await further developments. The patient was first seen by one of the writers about twelve and one-half hours after the shooting. The patient was in no apparent pain and in good spirits, but having that anxious expression of one seriously ill. His temperature was 100 F., pulse 120, blood pressure 120/80, and respirations 24. The respirations were rather shallow and grunting in character, due to the splinting on the right side. The abdomen was rounded, tympanitic, quite rigid and tender throughout, but especially over the right upper quadrant. There was a bullet wound in the right upper quadrant, just missing the lower border of the rib cage and a little lateral to Robson's point. The patient was too tender and rigid to palpate the liver edge, but assuming it to be at a normal level it was felt that the bullet had passed below the lower margin of the liver and would consequently have to pass through at least one hollow viscus. The bullet did not emerge through the back, but there was a tender point in the back, indicating that the bullet was lodged in the kidney region. The patient was unable to void, but upon catheterization a pint of normal urine without any blood was obtained.

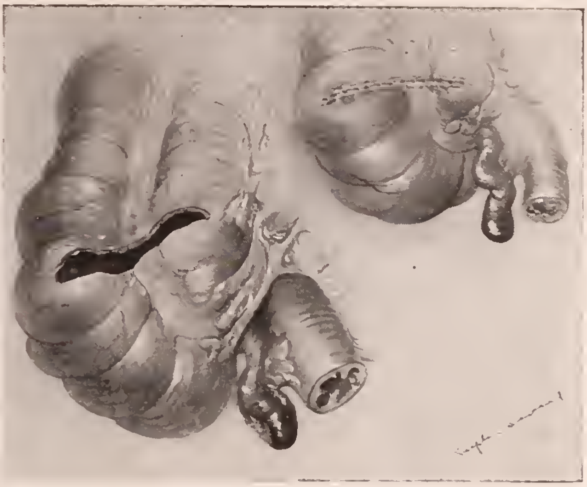

Fig. 1.—Injury to cecum and repair.

In view of the location of the bullet wound, it was felt that there was only one course to pursue, namely, exploratory laparotomy.

The patient was given a quart of glucose solution intravenously while waiting for the operating room, and a right pararectus incision was made with the upper end at the bullet wound. This was done and the abdomen opened under local anesthesia with the idea that we would look in, and if no contamination or hemorrhage was present the belly could be closed with no appreciable added risk. Upon entering the peritoneal cavity, gas, feces and blood began to pour from the incision, so the patient was given ether and the surgery continued.

It was found that there was a bleeding point in the mesocolon, also two perforations in the transverse colon, which were leaking bowel content. The anterior perforation was immediately closed, after which the bowel was rotated to expose the posterior perforation, which was then closed also. Further exploration showed the bullet had then passed completely through the ascending colon just below the hepatic flexure, and the anterior opening was leaking fecal material. This opening was closed; and in order to locate the wound of exit, from the ascending colon, it was necessary to mobilize the ascending colon by separating it on the lateral side at the peritoneal reflection and rolling it mesially until the posterior wound was found. In doing this a retrocolic or retroperitoneal collection of blood, contaminated with feces, was encountered. This wound was then closed, and the abdomen cleaned, so far as possible, with the aid of suction and packs. There were no perforations of the small intestine.

A small drain was placed in the retrocolic pocket, above described, and the abdomen closed around a small catheter through which was injected 200 cubic centimeters of

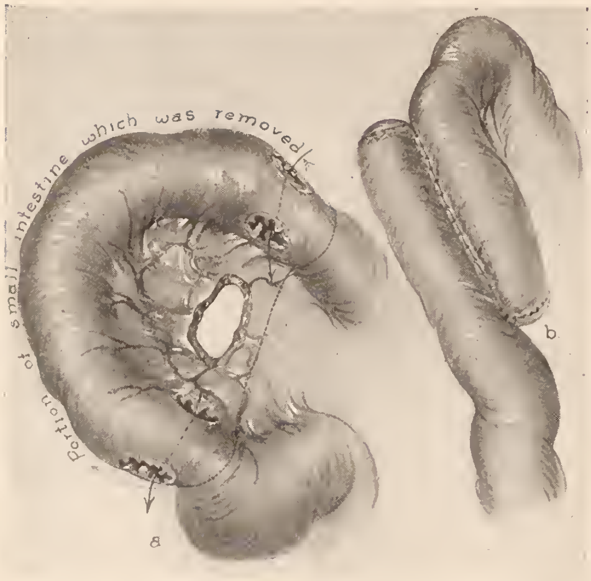

Fig. 2.—(a) Injury to small bowel, showing two points where bowel was almost transsected (bullet holes should be larger than in figure). Hole in mesentery destroyed blood supply to this loop. Dotted line in (a) shows where resection was made. (b) Side to side anastamosis.

amfetin. The patient was returned to his room with his pulse still 120 and blood pressure 130/80, having stood the operation well.

He was given a prophylactic dose of polyanaerobic serum and more glucose intravenously, and saline by hypodermoclysis. A nasal tube was passed to the stomach and connected with continuous suction bottle. He was given water freely by mouth, which was a source of much satisfaction to him even though it was immediately syphoned out through the nasal tube.

The patient progressed satisfactorily until the fourth day, when he had a chill and the temperature went up to 104.8. On the fifth day a definite consolidation could be elicited at the base of the right lung and râles at the base of the left lung. Fecal drainage then appeared at the former site of the drain, and continued. The patient gradually grew worse and expired on the eleventh day, in spite of all that could be done.

Postmortem showed pneumonia of bases of both lungs, fecal fistula from anterior wound of ascending colon, peritonitis, and paralytic ileus.

Comment.—This case should have been operated immediately after admission to the hospital. The fecal fistula should have been avoided by more careful closure or possibly by not using any drain. The pneumonia might have been unavoidable; but the use of oxygen and carbon dioxid was not tried until it was developed. The peritonitis and ileus could have best been avoided, though not guaranteed, by earlier operation.

* * *

Case 4.—Police officer, age 28, was shot by .41-caliber pistol while on duty, the bullet entering the left side, just above the iliac crest, and emerging on the right side through the upper margin of the ilium.

He was taken to the sanitarium, where he arrived about twenty minutes later, in a condition of moderate shock. While preparation was being made for operation, he was given preoperative hypodermic of morphin and atropin, and a quart of glucose solution intravenously. He was taken directly to the operating room upon arrival, and the preparation made there. A laparotomy was done as quickly as possible, saline being given by hypodermoclysis during the operation.

A midline suprapubic incision was made and, though little time had been lost in operating, the abdominal cavity already contained much blood and considerable spilled intestinal contents. The hemorrhage, which is the first consideration, was found to be coming from a transsected artery to a loop of small intestine, as indicated in Fig. 2. While ligating it, rubber-covered clamps were placed so as to prevent further leakage from this loop of bowel, which had almost been transsected at two points. (The illustrations, which of course were made later, do not properly show the amount of damage to the bowel, as the holes were much larger in proportion to the size of the bowel.)

Then, starting at the ileocecal valve in order to systematically locate all lesions, it was found that there was one hole in the cecum, just above the ileocecal valve, and eight holes in the small intestine. The bullet did not enter and leave the cecum, but cut across the anterior surface, as indicated in Figure 1. The descending colon escaped injury. Then inspecting every inch of the small intestine, beginning at the ileocecal valve, the first injuries were found to be those pictured in Figure 2, and the last in Figure 3.

The injury to the cecum was repaired, first with a locked-stitch and then inverted by a continuous Lembert of gastro-intestinal suture. The loop of small intestine in Figure 2 was so badly damaged, being almost transsected, and the blood supply so cut off by the transsection of the artery in the mesentery, that resection had to be done in spite of the fact that such a procedure is recognized as greatly increasing the mortality. This was rapidly accomplished by tying the intestine proximal and distal to the damaged part, and cutting between the ties on the preserved part and clamps on the part to be removed. The tied ends of the bowel were then inverted, as an appendix stump with linen. A side-to-side anastomosis was then rapidly done in the usual way. The only other feature of the procedure that was unusual was the closure of the two holes, as in Figure 3. They were larger and a little closer together than is indicated in the figure, and a simple repair was impossible, for the section of tissue between the holes would not hold for repair of the two holes separately. The patient, too, was already so much shocked that another resection seemed more than he could stand; hence, to lessen the time consumed the two holes were converted into one by cutting out, with scissors, the band of tissue between them. The gut was then knuckled in, closing it transverse to the axis of the gut, as illustrated. Thus, instead of narrowing the gut at this point, it was actually wider in its internal diameter, and the procedure consumed but very little time.

When we were sure there was no further damage, the abdomen was cleaned by suction and packs and made ready for closure. The next question was to drain or not to drain. Not many years ago no surgeon would have hesitated on this point, for all would have drained. We did not drain, but merely left a small rubber catheter emerging from the lower angle of the incision through which 200 cubic centimeters of amfetin was injected after the abdomen was closed. The catheter was withdrawn, being left only for injecting the amfetin.

The patient was sent to his room in fair condition, but with a pulse of 140, though of fair quality, and blood presssure of 100/75. The hypodermoclysis started in surgery was continued in his room and intravenous glucose again started. By the time a donor could be located and grouped he had so improved that a transfusion was postponed.

He was given a prophylactic dose of polyanaerobic serum and Edwenil was started according to directions, with the idea that it would do no harm and might stimulate some protective reaction. He was also started on inhalations of oxygen and carbon dioxid at frequent intervals as a prophylactic against atelectatic pneumonia. His postoperative course was briefly as follows: 8 p. m.: Glucose, 2,000 cc. intravenously. Saline, 2,000 cc. hypodermoclysis. Oxygen and carbon dioxid at intervals.

First postoperative day—9 a. m.: Glucose solution, 1,000 cc. intravenously. Oxygen and carbon dioxid at intervals. Maximum temperature, 102.4; pulse, 128. 5 p. m.: Saline, 1,000 cc. subcutaneously. 9 p. m.: Glucose solution, 1,700 cc. intravenously.

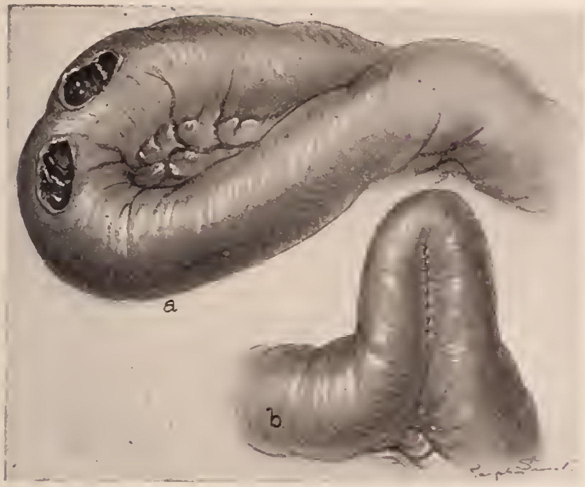

Fig. 3.—(a) Showing bullet holes in bowel. (They should be larger in proportion to size of bowel.) The portion between the two holes was cut away, converting them into one hole. (b) Method of closing the holes after conversion into one.

Second day—3 a. m.: Saline, 1,500 cc. subcutaneously. 9 a. m.: Glucose, 2,000 cc. intravenously. Nasal tube to stomach and connected with continuous suction. Water permitted ad libitum by mouth and syphoned off through tube. Fluid returning is bile-stained. 9 p. m.: Glucose solution, 2,500 cc. intravenously. Maximum temperature, 102.4; pulse, 130.

Third day—10 a. m.: Glucose, 2,000 cc. intravenously. 10 p. m.: Glucose, 2,500 cc. intravenously. Temperature, 101.4; pulse, 106.

Fourth day—10 a. m.: Glucose, 1,150 cc. intravenously. 6 p. m.: Glucose, 1,650 cc. intravenously. Temperature, 100.8; pulse, 96.

Fifth day—About the same as above.

Sixth day—Same as above. Water freely by mouth, syphoned off by nasal tube. On the evening of the sixth day, mineral oil, two ounces, instilled rectally. No enema had been given up to this time. Intravenous glucose continued. Broth and strained fruit juices by mouth. At first they were syphoned off by the tube, but later the tube was clamped for fifteen minutes and then opened. As this caused no upset, it was then clamped for longer periods after taking various fluids.

Seventh day—S. S. enema given and first bowel movement obtained since operation. Fluids now handled by mouth, so intravenous and hypodermoclysis discontinued.

Eighth day—Stomach tube removed.

From this point on the progress of the patient was uneventful, his diet being gradually increased to regular tray.

He was discharged from the hospital in good condition on the twenty-third day, and has since resumed his duties as a traffic officer.

Comment.—This patient owes his life to the fact that he was operated upon immediately, for otherwise he would have died of hemorrhage. Moreover, a delay would have increased his chances of succumbing to peritonitis had not the hemorrhage been fatal.

COMMENT

The closure without drainage certainly lessened his chances of postoperative hernia, wound infection, and adhesions. This point is not agreed upon by surgeons, and according to questionnaire replies from members of the American College of Surgeons, as published by Rhodes and Fernald in February of this year, more would have drained than would have closed without drainage. Rhodes, I think, rightly concludes that:

1. It is impossible to drain the abdominal cavity adequately.

2. Drainage probably aggravates the spread of infection.

3. Drainage encourages the formation of adhesions.

4. Drainage prolongs healing and predisposes to hernia.

5. Drainage increases the chances of fecal fistulae.

The liberal quantities of glucose and saline, I feel, are extremely important, for fluids are essential, saline is needed to replace losses where continuous suction from the stomach is prolonged, and the glucose furnished valuable, ready to use, calories.

The continuous suction certainly has been a tremendous aid since its introduction, and not only adds to chances of recovery but adds greatly to the patient's comfort, permitting him to take fluids by mouth freely, where, as in this case, vomiting was eliminated and distention minimized.

The length of time the intestinal tract should be kept as nearly at rest as possible varies with the level of the perforations.

The systematic examination of the intestinal tract is extremely important, for it is very easy to overlook some lesions. Out of twenty autopsies performed in Wilson's series of cases that had been operated upon, he was surprised to find that in ten cases visceral injuries had been overlooked at the time of operation. Billings and Walking reported nine cases of overlooked injuries in forty-five autopsies. Anyone who has had experience in operating upon these injuries can appreciate how easily this error may be committed. The patient is in a critical condition, the field is somewhat obscured, and the operator must complete his job in the shortest possible time.

Resection of bowel should be avoided unless it is imperative, for it adds greatly to the mortality. In every case in Prey and Foster's series necessitating resection of intestine, the patient died.

The postoperative care and nursing are extremely important factors in these cases, but no amount of it will take the place of early operation.†

Medical Building.

DISCUSSION

George K. Rhodes, M. D. (490 Post Street, San Francisco).—The case histories submitted by the authors in their review of this problem are excellent examples of the difficulties encountered.

The surgeon who assumes the care of these patients must exercise his keenest judgment in (*a*) preoperative diagnosis, (*b*) preoperative preparation, (*c*) operative technique, and (*d*) intelligent postoperative care.

Preoperative Diagnosis.—We must always keep in mind the topographical anatomy of the abdominal cavity and its associated organs. I have seen several fatal issues in which a gunshot wound of the fifth or sixth interspace was wrongly diagnosed as entirely a chest wound, and so conservatively treated. We must remember that any gunshot wound of the left chest, as high as the fourth interspace, has probably also penetrated the stomach. The range of the bullet indicates the probable structures involved, and also directs the location of the exploratory incision. If there is no point of exit, the x-ray should be used to determine the course of the bullet. X-rays are also of great value in showing a pneumoperitoneum which, if present, indicates a perforation of the gastro-intestinal tract. Each patient should be catheterized to rule out involvement of the genito-urinary tract. The physical examination of each patient will, of course, vary, due to many factors, such as the psychic phases, amount of hemorrhage, and the character of the contamination from the gastro-intestinal tract. Generally speaking, perforations of the empty cardiac end of the stomach may show very little immediate evidence of general peritonitis; however, those of pyloric end may simulate a perforated peptic ulcer. The more fluid content of the small bowel usually gives more peritoneal irritation than that of the more solid content of the large bowel. These factors are, however, largely for academic discussion. The diagnosis of even a possible gunshot wound of the abdomen justifies an immediate laparotomy. It is far easier to explain negative laparotomy findings to the patient than to give excuses to the coroner.

---

† The writers are indebted to Dr. E. Larson for his assistance in the operating room on Case 4.

Preoperative Preparation. — The simpler methods of combating shock are often the most efficacious. Psychic rest, warmth, and sedatives should be a routine. If the patient's condition seems alarming, these measures may be supplemented by administration of fluids by clysis or intravenously. It is obvious that the too free and rapid use of fluids and circulatory stimulants are to be avoided, for they may defeat nature's attempt to control the internal hemorrhage at its source. When the operation is begun, the fluids may be given with greater safety. The dangers of severe hemorrhage before and during operation must be anticipated, and the patient's blood grouped and several possible donors made available.

Operative Technique.—Operations of this type often tax the skill and judgment of the most experienced surgeon. The novice in surgery with poor hospital facilities will probably do more harm than good in most instances. With most patients, novocain block, supplemented by ether or gas and oxygen, will be the anesthetic of choice, for complete relaxation affords the best opportunity for adequate exploration. In specially selected cases spinal anesthesia is most preferable. Surgery should consist of (*a*) immediate control of hemorrhage; (*b*) systematic and thorough exploration of the gastro-intestinal tract from esophagus to anus; and (*c*) control of hemorrhage from spleen, liver or kidney. Perforations should be closed, taking care not to occlude the lumen. If several perforations be found in a given segment, it is usually better to resect.

I heartily agree with the authors regarding the advisability of closing these cases without draining the abdominal cavity. This has been our policy in the San Francisco Emergency Hospital for several years, and our very, very low mortality is undoubtedly due in no small measure to this practice of nondrainage. The abdominal wound and retroperitoneal spaces should be freely drained to avoid severe and sometimes fatal sepsis from streptococci and anaerobic infections.

Postoperative Care.—These patients must be given intelligent postoperative treatment for spreading peritonitis, even though it never manifests itself. The Connell suction type of drainage through a nasal tube is undoubtedly our best prophylactic measure against paralytic ileus and postoperative mechanical obstructions. The fluid and salt balance should be maintained to the extent of 3,000 to 4,000 cubic centimeters a day.

⁂

H. Glenn Bell, M. D. (University of California Hospital, San Francisco).—The points brought out by Doctors Binkley and Cole are well taken. One only has to work for a time in an emergency hospital in a large city to realize that many of the patients with gunshot wounds may show little or no clinical evidence of injury to a hollow viscus. At operation, however, one finds several perforations of the bowel. At times it is difficult to convince the patient that operation is necessary. In the examination one should not forget to percuss the liver to see if dullness is absent because of gas under the diaphragm. The use of a catheter will almost always indicate the presence or absence of an injury to the genito-urinary tract. At the Cincinnati General Hospital there was a hard-and-fast rule that, in every case of gunshot or stab-wound of the abdomen, a laparotomy must be performed unless it could be proved beyond doubt that the peritoneal cavity had not been entered. Such proof was hard to obtain without operation. Many times we found perforations when we did not expect them. Another requirement was that lavage of the stomach must be done before surgery, if general anesthesia were used. If a patient has a full stomach, as many of these have, he may vomit under anesthesia, with disastrous results.

In operating, Doctors Binkley and Cole stress the care which must be used in making sure that no perforation is overlooked. I should like to remind you that much time may be saved by closing the abdomen with through-and-through silver wire sutures instead of in layers, as pointed out by Halstead, Reid, and others. These men, too, felt that the abdominal cavity should not be drained; with this view I agree absolutely.

It seems to me that the doctors have outlined the correct procedures in handling these cases even though they were able to carry them out in only one case. Their case reports indicate clearly the many difficulties in the way of proper treatment, and the outside influences which must be considered. In two cases there were, perhaps, too many consultants; in one case the family prevented proper treatment.

⁂

John Homer Woolsey, M. D. (Woodland Clinic, Woodland).—Gunshot wounds of the abdomen are not as well handled as they could be, and so a paper covering the subject in an attractive and instructive manner, with illustrations of and comments upon the two types of medical attention given, is most worth while.

The "watchful" or "prayerful" waiting attitude assumed in instances of gunshot wounds of the abdomen is exactly as logical as the ostrich fleeing from danger by burying its head in the sand. Prompt, thorough, and careful exploration is paramount, but it should not be done until after proper preoperative study. In order to prevent additional shock, the abdominal viscera should be gently manipulated by inspecting a section of intestine at a time and returning it to the abdominal cavity, while warm, moist packs are kept over all exposed viscera.

A proper preoperative study includes an examination of the blood picture, the blood pressure, and the pulse rate; a study by roentgen rays as to the course or position of any foreign body, and thereby locating the viscera or tissues which might be involved; an examination for hematuria in case of a possible bladder or kidney injury; an examination of the voluntary movements and the deep reflexes for possible spinal-cord injury.

Shock is present in the majority of these injuries, so preparation should be made to give fluids or blood transfusions at once, or during the surgery, as indicated. A wide choice in anesthesia allows one to proceed early. A spinal anesthesia not higher than the fifth thoracic is our choice. Contamination occurs in the first few hours, and inflammatory process develops later; so the more prompt the surgery, the better the chance for primary healing and a successful outcome for the patient.

⁂

Doctor Binkley (Closing).—I was glad that Doctor Rhodes mentioned x-rays to show pneumoperitoneum, for at times we do get striking pictures that are pathognomonic. These may be taken with the patient in the upright position or on the side, and if positive there is no doubt; but if negative there is still doubt, and in either case laparotomy must be done. I agree that if the delay or the handling of the patient are not contraindicated, the procedure is of academic interest and should be done.

POISONING POISONOUS SPIDERS*

AN EXPERIMENTAL INVESTIGATION IN THE CONTROL OF THE BLACK WIDOW SPIDER (LATRODECTUS MACTANS)

By Emil Bogen, M.D.
and
Russell N. Loomis, M.S.
Olive View

Discussion *by Russell M. Gray, M.D., Indio; George Elwood Jenks, Los Angeles; W. J. Baerg, Arkansas.*

Poisoning from the bite of the black widow spider has been reported with increasing frequency in recent years. More than two hundred cases have been tabulated by thirty different writers since 1932, bringing the total recorded to date to over six hundred. Several deaths from this cause are now being listed annually in one state alone, and no part of our country appears to be entirely free from this dangerous creature. Part of the increase in the number of bites recorded is undoubtedly due to the wider appreciation of their possibility, with the consequent recognition of cases that would have been otherwise missed, both by the physician and by the public. A part may be ascribed to the change in habitat of many of these spiders from rural to urban sites, with consequent increase in the opportunities for human contact. Many workers, however, believe that there has been a real increase in the number of these spiders throughout the United States, either because of weather conditions, and more abundant food supply, or because of the destruction of the natural enemies of the spider.

SYMPTOMS

The publication of more than a score of articles annually since 1926 dealing with this subject has undoubtedly contributed much to awaken the medical profession to the possibilities of diagnosis of this condition. The typical history of a bite by a black widow spider, followed within an hour by increasing pain and muscle spasm, leading to a picture simulating an acute abdominal condition, with rigidity, fever, leukocytosis, and even nausea and vomiting, is becoming recognized as a distinct clinical entity. The presence of muscle spasms in the extremities, the increased blood pressure and spinal fluid pressure, the absence of true tenderness in the painfully contracted muscles and the profuse perspiration, aid in the differential diagnosis. Such exceptional manifestations as shock or circulatory collapse, local or generalized skin eruptions, edema or necrosis, and residual nerve lesions, although occasionally reported, are not commonly encountered and should not be stressed in the description of the usual case.

TREATMENT

Effective treatments for patients suffering from arachnidism, or black widow spider bite poisoning, have been developed during the past decade, but are still too little known by the medical profession at large, and articles still report and advise the application of the numerous ineffective treatments of the past. The mental reassurance and avoidance of operative intervention that follows making the correct diagnosis gives this procedure a real therapeutic value. Local treatment should be confined to a simple antiseptic application, as the scarification and cauterization or suction useful in other kinds of venomous bites have no value in this condition.

Pain.—Relief of pain may be secured by the use of hydrotherapy, by spinal puncture, by the intravenous injection of 20 cubic centimeters of a 10 per cent solution of magnesium sulphate, and especially by the intravenous injection of 10 cubic centimeters of 10 per cent calcium chlorid or the intravenous or intramuscular injection of 10 cubic centimeters of a 10 per cent solution of calcium gluconate, more effectively than by the administration of opiates or other sedatives.

Serum Treatment.—Serum treatment has been developed against the bite of the black widow spider, both with the use of human serum from subjects who had previously recovered from a typical case of spider-bite poisoning, or with serum obtained from small animals that had been subjected to the bite of the spider and had recovered. No commercial sources for such serum are now available, but in particularly severe cases it may be obtained from the Los Angeles General Hospital, or from Dr. F. E. D'Amour of Denver, or from the Olive View Pathology Laboratory. The results, while still encouraging, are not conclusive, and in view of the fact that institutions using the other modern treatments report scores of cases with no deaths, and with rapid amelioration of symptoms, the general use of such serum is probably unnecessary.

BLACK WIDOW SPIDER'S FOOD

The black widow spider obtains its nutrition solely by sucking the body fluids out of the still living victims, utilizing for this purpose its own offspring as well as its mate or others of its species, other arachnids, and a wide variety of insects, including the common house fly, other flies, crickets, moths, grasshoppers, beetles, etc. Occasionally, even small vertebrate forms may be attacked. Usually the spider attempts to entangle the victim in its web, and tie it up well, then taking its meal off the still living victim at leisure. The venom of the spider is probably especially useful in paralyzing victims while they are being thus wrapped for later consumption. Although in its rôle as destroyer of flies and other noxious insects the black widow may be of service, it would seem that other safer measures should be preferred.

NATURAL ENEMIES OF THE SPIDER

Natural enemies of the black widow are numerous, but seem to play a restricted rôle in limiting their numbers. Birds and lizards probably destroy a few of the spiders, but owing to the habits and habitat of the black widow few of them are accessible to these agents. Wasps, particularly the digger or mud-dauber wasps of the Sphex genus, make use of the black widow as food for their

young, and probably are a much more important factor in their control. Scorpions, solpugids or vinegaroons, centipedes and tarantulas, as well as the mole cricket and certain other insects, may sometimes kill the black widow; but in nature such encounters are probably uncommon, and the victory may be on either side. Several insect parasites on the egg of the spider have been described, but none seems to be as yet of real importance. Diseases of the spider are quite unknown, though certain fungi are occasionally found growing on defunct specimens.

The control of the black widow spider has, hitherto, received little serious investigation. The casual references to the effects of certain agents are, on investigation, often found to be inaccurate and misleading. In view of the increasing recognition of the dangers of poisonous spiders, and the frequent inquiries as to what to do about them, it was thought desirable to undertake a systematic investigation into the possibilities of destroying them.

DESTRUCTION OF SPIDER BY MECHANICAL MEASURES

Mechanical measures for the destruction of the spider are most generally advised. The broom, fly-swatter, shoe, or stick, have all had their quota of victims. In handling the egg sacs, it may be well to remember that the spiders may be alive, hatched in the sac for days before they emerge, and that the careless opening of the egg sac may be the signal for the emergence of hundreds of spiderlings. The difficulty of reaching the spider in inaccessible places by such simple mechanical means, the danger of damaging other property, breaking windows, etc., and the low visibility of the spider in its usual dingy and sheltered habitat, all detract from the general application of simple mechanical measures, which remain, however, the most effective so far discovered.

The spider appears little sensitive to odors, sounds or sights, but is affected by bright moving lights and particularly by vibration or mechanical stimulation. It has a slight negative phototropism, preferring the dark times and places, and a slight negative geotropism, so that it hides in the higher portions of the webs, but these tendencies are often not exhibited. It prefers a secluded, undisturbed location, and will often move elsewhere if repeatedly disturbed, or if its web is repeatedly broken.

HOW BLACK WIDOW SPIDER BITES MAY BE AVOIDED

The avoidance of the bite of the black widow spider depends primarily upon avoiding contact with the spiders. In earlier times, they were most

often reported in the fields, in bushes, under twigs or logs, and in other rural sites. Their webs have been found in the tunnels of ground squirrels and other burrowing animals, where they may be protected during the cold winters. They have also been found under stones or rocks or in the crevices in stone walls. Intensive cultivation of the land makes these sites less tenable. Most of the earlier human victims were bitten while in wooden outdoor privies, by the spiders which had built their webs under the seat. Making the seats of outdoor toilets on hinges so that they may be inspected and cleaned on the underside, has been accordingly recommended. Wherever possible, outbuildings should be well lighted and screened. The young black widow may pass through ordinary fly screen, but it is not so apt to make its web in places where other forms of life cannot be found for food.

More recently the black widows have been described in garages, chicken-houses, on porches, under chairs, tables, or stairways, under the eaves and beneath the rafters in cellars and attics, in shelves and closets, and under boxes, boards and

rubbish heaps in general. Accordingly, all rubbish heaps should be destroyed and dark, cluttered corners in cellars, attics, garages, etc., should be cleared up as much as possible. Frequent forays, destroying the webs and killing spiders when seen, may discourage them from making their home near human habitations.

The wearing of white gloves, a single thickness cotton glove such as is sold at the ten-cent store, is sufficient; wearing white clothing against which the black spiders may be easily detected, a large white hat or cap, a collar turned up at the neck, and trouser legs closed at the bottom, or knickerbockers, may be recommended while working in the vicinity of the spiders. A mosquito or bee net over the face may sometimes be advisable, particularly when crawling under houses or in other dangerous places.

Fire has been used as a means of exterminating the black widow, but it is usually of limited value. Rubbish piles may be burned as a preventive, but the spider is usually quick enough to escape the flame unless closely watched. Although certain spiders have been reported to skip over boiling water at hot springs, it appears that the black widow is more susceptible to heat, and under certain conditions boiling water or steam may be used effectively to get rid of them. On the other hand, drowning with water or a bland oil usually leads to merely temporary cessation of movement, the spider feigning death, but coming to life and activity again when it dries.

TECHNICAL PROBLEMS

The evaluation of insecticidal, or rather arachnicidal properties of substances against the black widow is fraught with unusual difficulties. Postmortem movements of the spider, especially under the influence of air currents or when a wisp of web attached to one of its legs is touched in an invisible portion, often makes it appear as if the spider were alive long after death has occurred. The characteristic contracted death posture, sometimes helpful in this direction, may be absent after some modes of killing. On the other hand, the practice of feigning death, an instinctive ruse with the spiders when disturbed, often misleads the observer into thinking that the spider is dead when it is only "playing possum." Although the spider may continue to mimic death in the presence of chemicals, or when shaken or turned over in the jar or cage, irritation of her body, particularly the cephalothorax, with a firm, fine, wire point. almost invariably causes active movements. Such tickling of the spider, therefore, forms a valuable aid in determining that it is really dead.

The restricted dietary of the spider, consisting only of the sucked-out body fluids of living insects, makes it escape most of the common stomach or feeding poisons placed in its vicinity, while its ability to "hold its breath," and low respiratory requirements, makes it resistant to many respiratory poisons which are effective against common insect pests. The hard, chitinous covering of the spider is resistant to many contact poisons, and its ability to shed a leg and to regenerate a new one enables it to escape many mechanical injuries.

EXPERIMENTAL PROCEDURES IN FUMIGATION

The varied natural habitat of the spider makes it inaccessible to many simple measures. No one method has been found which is equally effective under all circumstances. The duplication, in laboratory conditions, of the natural habitat was found difficult and uncertain. For this investigation, after a number of attempts with various set-ups, two types of experimental conditions were studied—the closed-jar method to determine fumigating efficiency of the different substances in a completely enclosed space, and the open-cage method to determine the efficacy of simple contact sprays.

For the study of the fumigating action of substances against the black widow, glass jars 6½ inches high and 2¾ inches in diameter, with a capacity of 500 mils and with a tight-fitting screw lid, were used. The spiders were placed in the jars, and allowed to spin a web in the bottom of the jar. The jars were then inverted and the lids removed, the spider then remaining in the web at the top of the inverted jar. The substance to be tested was then placed on a small piece of cotton on the lid, and covered with screen wire to prevent the spider coming in direct contact with the material. The lid was then screwed back on the jar, and kept in an inverted position, thus placing the spiders about six inches from the substance tested. The time was recorded, and a careful watch maintained for many hours for the time when the spider might drop from the web, and also when all signs of life might disappear, so that the duration of exposure required to kill the spider might be recorded. Varying amounts, 1.0, 0.1, 0.01, 0.001 and/or 0.0001 grams or mils of the substances tested, were used, diminishing the amount until the killing power was lost.

INSECTICIDAL MIXTURES

More than fifty different pure chemicals or mixtures were tried by the closed-jar method. For convenience these are divided into five groups.

1. The following substances failed to kill the spiders, even in concentrations of one gram to the jar, the highest amount used:

Acetone, antimony potassium tartrate, calcium oxid, calcium chlorid, calol, cobalt chlorid, soap solution, sodium fluorid, sulphur, nitrobenzene, pine oil, pyrethrum powder, triorthocresyl phosphate, Union garden spray, water.

Despite the fact that several of these have been highly lauded as effective for killing spiders, as well as insects, our experiments indicate that they are far too weak to be of any value for fumigating purposes against the black widow.

2. The following substances were found effective in concentrations of one gram to the jar, but not less, which would correspond to about two ounces per cubic foot:

Alcohol, methyl, ethyl, and butyl; Beechwood creosote, carbolic acid creosote, or crude coal-tar creosote; carbon disulfid, sulphuric ether, formaldehyd, kerosene, lysol, black leaf 40, Digas, Premek spidercide, pyrocid 20, vaposector fluid.

Although some of these agents may still be of value if placed directly on the spider, they cannot be expected to be very effective as fumigants when merely placed in the vicinity of the spider. In view of the reports that they might act as repellants, causing the spider to go elsewhere, some of them were placed in double jars containing spiders, the jars being connected at the necks so that they afforded a total length of more than a foot. There could be noted little tendency of the spiders to go away from the materials. Since the concentrations of these substances required to kill the spiders is higher than would be developed in the open, it is felt that little reliance may be placed on the use of these substances, particularly the creosotes, as safeguards of outdoor privies and similar locations.

3. Substances somewhat more effective, capable of killing in amounts of 0.1 gram per jar, or about two grams per cubic foot, included:

Alcohol, isopropyl and n. hexyl; benzene, carbon tetrachlorid, chloroform, gasoline, grainosect, lethane, mustard oil, o-dichlorobenzene, Pharo spider kill, pyridin, toluene.

The amounts of these substances required for fumigation purposes against the spider are still excessive for practical use.

4. As little as 0.01 gram per jar, or about a pound for a small room, was sufficient for the following substances:

Alcohol, isoamyl; cresol, Destruxol, Hunt's insect powder, mononitrobenzene, naphthalene, paradichlorobenzene, phenol, potassium cyanid, sodium cyanid, sulphur dioxid, xylene.

5. Even smaller amounts sufficed for calcium cyanid, benzaldehyd, and dimethylanilin.

SPRAYING METHODS

The usual habitat of the spider is inaccessible to closed fumigation methods, as sufficient concentrations of the fumes cannot be obtained to be effective. A spray may be expected to give better results under such conditions and, accordingly, a method was devised for spraying the spiders in the open air under constant conditions, in special wire cages, as follows: Small wire cages, three and one-half inches tall and two inches in diameter, were made of one-eighth inch wire mesh hardware cloth, closed at the bottom with screen wire and at the top with a large stopper or tin lid. The spiders were placed in the cages, the cages suspended freely, and the substance to be tested sprayed at the spider through a No. 16 De Vilbiss atomizer at a distance of about two inches, usually giving two or three bulbsful of air to each substance, or about 60 cubic centimeters of spray. The time of spraying was noted, and the spiders examined repeatedly so that the time when all signs of life disappeared could be recorded. In order to guard against feigned death, the spiders were irritated with a small wire from time to time.

It was soon realized that no spray could be effective if it did not actually reach the spider, and that no substance so far tried would have any effect if merely sprayed on the web or in the vicinity of the spider. Some sprays appeared to irritate the spider and increase its motions, but these were not entirely consistent. The light spraying of the atmosphere, so effective with fly sprays of pyrethrum against the common house fly, is useless against the black widow.

Inasmuch as a heavy spraying must be used, the inhalation of the spray by the person using it is almost unavoidable. There must be care, therefore, to avoid the use of substances that might be toxic to the user. Cyanid sprays are accordingly ruled out from the start, although they are perhaps the most effective.

Isoamyl alcohol and lethane, although both quite effective and of comparatively low animal toxicity, both may give rise to headaches and other symptoms if inhaled in high concentrations. By the use of lower concentrations, such as one per cent of these in kerosene, however, this disadvantage is reduced, and perhaps the most effective sprays to be advised are these. Numerous commercial sprays tested were generally weaker than these two. Aqueous sprays were, unfortunately, quite disappointing in their results, 10 per cent sodium arsenite and cyanids being the only effective aqueous agents found. The addition of lime was not found to have any effect on the potency of kerosene.

CHOICE OF FUMIGANT

There are many factors affecting the choice of a fumigating agent after its effective concentration has been determined. Most important is the possible effect on the life and health of humans and animals who may be exposed to it, accidentally, or before, during and after the fumigating process. As a crude test of the dangers from these agents, 0.1 cubic centimeter of each substance was injected subcutaneously into a laboratory mouse. Those causing death in the mice within a few days may be readily suspected of being dangerous if used without special precautions.

Not only the drugs that kill mice, however, require scrutiny. A number of other substances, sublethal in effect, are capable of producing profound damage, headaches, liver injury, etc., to all or certain susceptible exposed individuals. Such dangers to health require primary consideration.

The danger of fire or other damage to property is also important. Highly inflammable substances must, therefore, be used with caution. Most fly sprays are of mineral oil or kerosene bases, and are inflammable. Many organic substances may form explosive mixtures with air.

The danger of corrosion, bleaching, injury to plants and other materials must also be considered.

The cost of the substance to be used, both absolute and relative to the task required, and its ready accessibility and keeping properties, also merit consideration. The effect of temperature, of humidity, and the ease of application of the material, likewise need some thought.

CONCLUSIONS

In general, we may conclude, on the score of effectiveness, cheapness, safety and simplicity, that, for fumigation purposes against the black widow, the following recommendations may be made:

1. For small boxes, chests, and similar enclosed spaces, naphthalene, the commercial moth-ball material, be used in amounts of two ounces of naphthalene to each cubic foot of space free.

2. For large, completely sealable chambers, fumigation with sulphur dioxid from sulphur candles, using a pound of sulphur for every thousand cubic feet of space, for at least one hour.

3. For storage places, where safety of humans may be assured, cyanid, using three ounces of calcium cyanid for each thousand cubic feet space, for at least two hours.

4. For open spaces, such as outdoor privies, or under houses, no fumigant or repellant has been found that is to be relied upon.

5. No commercial preparation has been found that offers any prospects of significant value as a fumigant or repellant.

6. For spraying purposes, ordinary kerosene was found to be effective, but the addition of a small amount, 1 to 10 per cent, of isoamyl alcohol, or of the commercial organic compound lethane, added to the rapidity of its action. It should be emphasized that no spray is effective unless it actually reaches the spider, and the more thoroughly the spider is wet by the spray, the more certain and soon is its death. Spraying the empty portions of the web appears to be of no value with any of the materials we have used.

7. Mechanical measures remain the cheapest and most readily applied tactics to consider in the control of the black widow spider. Under certain special conditions steam, fire, and even electricity, may prove applicable, while fumigants and sprays, as just discussed, have definite indications and limitations. The danger of the black widow, however, is sufficiently great to warrant the employment of any or all of these measures, as may be best adapted to the individual conditions encountered, while it is to be hoped that insect enemies or other natural control measures may be developed in the future.*

Olive View Sanatorium, Los Angeles County.

DISCUSSION

Russell M. Gray, M.D. (Hotel Potter Building, Indio). During the past few years a great deal of publicity has been given to the black widow spider. This has been occasioned by the greatly increased number of spider-bite cases given prominence by the newspapers and other publications, and also the fact that the black widow spider has evidently spread all over the country. This apparent spread, or increase in number of black widow spiders, can only mean that the method of treatment of these cases must be improved, and must be brought to the attention of all practicing physicians. In addition to that, it behooves the medical profession and other scientists to develop some means of eradicating the black widow spider.

Doctor Bogen's article sets forth, in concrete form, many of the difficulties which are to be encountered in developing an insecticide or an arachnicide which will be effective, but at the same time not too expensive.

Experiments conducted along this line in the Coachella Valley Hospital laboratory have made us realize that this spider has very few natural enemies capable of eradicating the pest. The very fact that it is found in dark places, usually inaccessible to the other forms of insect life, and that the bite of the spider quickly paralyzes and causes the death of other insects, makes us realize we are going to have to turn to some artificial means, such as Doctor Bogen has attempted.

Fortunately for the human race very few spider bites assume alarming symptoms. The majority of the cases can be treated and controlled by simple remedies which are available in all hospitals and the majority of doctors' offices. It is the rare case—and apparently there have been several of these throughout the United States—where, in spite of all treatment, the patient is apparently doomed to die, to which we are particularly turning our attention in the endeavor to develop a specific. After seeing the extreme suffering of one of these severe cases, we realize no stone must be left unturned to develop an effective and inexpensive arachnicide.

Recent experiments conducted at the Coachella Valley Hospital laboratory tend to show (although this has not been definitely proved) that the spider whose habitat is in dark, damp places is more poisonous than the spider living in the open. Because of the fact that these spiders are usually found under the houses, in outdoor latrines, around garages, and in other spots where it is impossible to limit the air space, it takes very little imagination to realize the tremendous problem facing us in the control of this pest.

Doctor Bogen has initiated the beginning of a very interesting and, at the same time, useful field; but it will take a great deal of experimental work and many trials and errors before anything is found which will be universally available, and at the same time within the reach of all, for the eradication of the black widow spider.

⁂

George Elwood Jenks (Spider and Parasite Research, Los Angeles County Health Department, Los Angeles).—"Poisoning Poisonous Spiders," by Doctors Emil Bogen and Russell N. Loomis, is so comprehensive and accurate that there seems to be nothing to add except, perhaps, a word about the recent successful propagation of the "lost" parasite—a rare and almost forgotten dipterous fly, the larvae of which feed upon the eggs of the black widow spider.

First found in Los Angeles in 1896, and described by Dr. A. Davidson in the *Entomological News*, Vol. 7, p. 320, Gaurax araneæ (Coquillett) apparently became so rare that it was practically lost to science for nearly forty years. When it was rediscovered two or three years ago, it was hailed by many scientists as a new species, but I was fortunate in obtaining the correct identification from

---

P. H. Timberlake of the University of California Experiment Station at Riverside.

This parasite oviposits almost exclusively upon the egg-sac of the black widow spider. When the larvae hatch, they penetrate the shell of the egg-sac, devour the hundreds of eggs or spiderlings within, pupate, and eventually emerge as adults to complete the cycle. Apparently these parasites have been somewhat outdistanced by the abnormal increase of Lactrodectus mactans during recent years, and must have the "boost" of artificial propagation in order to become an effective check upon that increase.

Several workers found this parasite and began experimenting in 1934, possibly earlier; but for a long time no one was able to get these flies to thrive, mate, and propagate under artificial conditions. It was only after two years of experimental work in my home laboratory, and with the present aid of the facilities of the Los Angeles County Health Department, that I finally reached the place where I could be fully confident of ultimate success.

The artificial propagation of these parasites by the thousand is now an accomplished fact. Before, however, they can be bred by the required millions, there are several more problems to be solved, mainly in regard to the development of a more perfect synthetic food for the larvae.

Nevertheless, the work has now reached a point where it seems assured that biologic control, together with chemical and mechanical methods—*and* popular education—can ultimately be combined to provide a practical and effective remedy for the black widow menace.

⁂

W. J. Baerg, Entomologist (University of Arkansas, Fayetteville, Arkansas). — Doctor Bogen has made another important contribution to the knowledge of poisonour spiders and he writes as one who has come into immediate contact with the subject.

The prevailing opinion that black widows have been rapidly increasing in numbers during the last two years, is based on facts, at least in the Middle West. Suggestions for so-called control measures are, therefore, much in demand, even though in some parts of the country spider-bite cases may be relatively uncommon. The presence of the black widow in even small numbers inspires fear, and there will be a widespread effort to reduce the sum total of this spider.

Natural enemies, such as other spiders, scorpions, wasps, and various predatores have been investigated by several research workers; but, in general, accounts agree that these preying insects play but a minor rôle. The blue mud-dauber, where it is abundant, is perhaps the most important of such natural enemies.

Severe winter temperatures are by some authorities believed to be fatal to black widows in the northern and central states; but, so far, evidence is lacking. Observations during the coming spring and summer may substantiate this opinion.

URINARY EXTRAVASATION*

By J. C. Negley, M.D.
Los Angeles

Discussion *by George F. Schenck, M. D., Los Angeles; A. A. Kutzmann, M. D., Los Angeles; H. C. Bumpus, Jr., M. D., Pasadena.*

URINARY extravasation, generally speaking, is an extensive destructive phlegmonous inflammatory process from pathologic conditions in or about the urethra, usually accompanied by gangrene of great extent, most often occurring after urethral disease such as stricture, calculi, abscesses, or periurethritis; but trauma, direct or indirect, with rupture of urethra or bladder, may play a part.

ETIOLOGY

Etiology most often occurs in urethrae weakened by stricture, with back-pressure making for dilatation and thinning of the walls with little resistance to infection. Unless a history and signs of recent trauma are present, one can most always be sure of an infectious origin. For convenience, the etiologic factors may be enumerated as follows:

1. Stricture (*a*) from antecedent disease, or (*b*) from scar tissue, following trauma.

2. Inflammatory process without stricture, as periurethritis, adenitis, littritis, cowperitis, periadenitis, with secondary necrosis and phlegmon.

3. The intact urethra without urinary infiltration, accompanied by massive phlegmonous gangrene, may simulate a true urinary extravasation so as to be indistinguishable from it until after operation. These cases, in my belief, are caused by the preliminary leakage of a few drops of infected urine, and the resultant edema, which closes off the opening; but the process goes on the same as though urine was present.

4. Trauma, direct or indirect, as from straddle falls, blows, automobile accidents, fractures of pelvis, hip, may lead to a slight laceration, a complete transverse severance of the urethra or rupture of the bladder. Many contusions, without actual disturbance of continuity, may prepare the soil for a virulent infectious necrotic process, which produces leakage and extravasation. Intercourse in those having stricture, in rare instances, may cause this condition.

5. Calculi, impacted so as to cause obstruction, may cause erosion necrosis enough to produce leakage.

6. Except in very immediate traumatic cases, bacteria play a major rôle. Colon, staphylocci, streptococci, and many varieties of anaerobes are mostly found. French observers have claimed that without the latter, gangrene cannot occur.

ANATOMY

To understand and correctly treat extravasation one must visualize the division of the pelvis into an external and internal compartment, with the triangular ligament at the dividing line. It is a dense fibrous wall, with a relatively thick anterior and thin posterior layer. The triangular ligament stretches across the pubic arch, attached in front to the symphysis pubes, laterally to the ischiopubic rami, which posteriorly offers insertion for Colles's fascia. Between the layers of triangular ligament are the nerves and blood supply of the penis, and within its borders are the membraneous urethra and ducts of Cowper's glands. Colles's fascia, sometimes called the superficial perineal fascia, is attached to the posterior border of the triangular ligament from which it sweeps back and down, separating the deep and superficial transverse perineal muscles, then forward under perineal, scrotal and penile skin, to fuse with the deep penile fascia at the root of the organ. This arrangement forms an anterior perineal triangular space open only at the base of the penis. Through this opening extravasation extends upward over the abdomen under Scarpa's fascia, which is the continuation of Colles's fascia over the abdomen. Scarpa's fascia, by its attachment to Poupart's ligament, prevents invasion of the anterior thigh. Therefore, extravasation anterior to the triangular ligament must be limited in the perineum by Colles's fascia, and on the abdomen by Scarpa's fascia. Thus the order of perineum, scrotum, lower abdomen, penis and groin extension is observed. Cases have been noted of extension to lower border of ribs and to axillae. Infiltration, originating behind triangular ligament, extends behind the prostate, invades the ischiorectal fossae, and may include the buttocks and inner upper aspect of the thighs, sometimes retroperitoneally to the kidneys. Intrapelvic infiltration, pointing anterior to urethra, results in a pre- or perivesical phlegmon.

---

* Read before the Urology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

Infiltration between layers of triangular ligament may go either to front or backward, more often in front. Extension of the process in any location is dependent on the duration and virulence of infection.

PATHOLOGY

The onset is a cellulitis, with vascular thrombosis, gangrene and perforation, generally near an old stricture, a contused urethra, a hematoma with pressure gangrene, a laceration or severance of urethra. Once loose in the tissue, infected urine incites phlegmon. Injected sterile urine does not produce this process. French observers hold that actual urinary infiltration does not always exist, but that the process is by bacterial invasion only (anaerobic), and that the fluid found is only an acute inflammatory exudate. Others have demonstrated 2 per cent urea in the fluid from the tissues at operation, and have concluded that the fluid was always urine. Acute or chronic pyelonephritis is frequently a concurrent pathology, and is often the cause of death. Most always perforation of urethra occurs at site of, or posterior to, a stricture, either from mechanical pressure of urine or acute local infection; but the latter is always present except in early trauma.

SYMPTOMS

Local tenderness, swelling, chills, fever, mental confusion, delirium, coma, and other signs of overwhelming toxemia are always present to a greater or lesser degree. The intensity of the symptoms is generally graded on the extent and duration of the phlegmon. Urinary obstruction, with partial or complete retention, is marked by the usual symptoms of that condition. Dysuria, difficulty, dribbling, hematuria, frequency, small stream, burning, may all or part of them be present, and are always a predominating feature unless coma is present.

DIAGNOSIS

Generally these cases reach us late enough so that, from the first case on, the diagnosis is easily made, from inspection and palpitation. A bulging perineum, purplish red scrotum, spots of green to black gangrene, with the characteristic odor. The picture may also be present on the abdominal wall. Urethral catheter will often show obstruction. Conditions simulating extravasation are edema of scrotum, from cardiorenal disease, diabetic gangrene, strangulated hernia with gangrene or cellulitis of scrotum and abdomen, scrotal or penile gangrene from streptococcus cellulitis.

TREATMENT

1. Cystotomy at once, regardless of location of extravasation (*i. e.*, anterior or posterior), placing de Pezzar catheter in bladder.

2. Follow with parallel, free, wide, handsome incisions to the depth of process, and from the perineum to the costal margin if necessary, including penis, scrotum, perineum, and abdomen, is unavoidable. Connect these incisions by burrowing under with a knife-handle or forceps. Connect with Penrose drains. Doctor Day has aptly termed this a "slasheotomy."

3. Above is for anterior extravasation. Some surgeons bisect the scrotum in addition. Personally it seems unnecessary, and I call your attention to the presented cases, with a mortality of 66 per cent when this is done, alone without other incisional drainage.

4. For posterior extravasation cystotomy and a dissection of the bladder from its bed if necessary, so that drains may be placed to bottom of pelvic cavity. Sometimes a drain connecting perivesical space, with the perineum to the outside by way of the ischiorectal fossae, may be of advantage.

5. Any attempt at dilating a stricture, repair, bladder-neck surgery, or even removal of impacted calculi, is foolhardy and unwarranted where any degree of infection exists. Very recent cases of trauma without infection may be occasional exceptions. In the cases I will cite, added operations were done ten times, with eight deaths.

6. External urethrotomy, on account of the difficulty of locating the urethra and the fact that one is working in an infected field, is mentioned only to be condemned.

7. When the patients reach the wards, one must be alert to keep drainage established.

8. When the patient has recovered from the shock of operation, continuous hot baths (temperature 99 degrees) of permanganate 1 to 10,000 is a benefit. We have kept patients in this bath for four consecutive days without danger. Thiersch solution also can be used in the bath. A heavy coating of vaselin over entire body keeps the skin from contracting and makes for comfort.

9. If exhaustion or other conditions force the patient to bed, hot moist permanganate or Thiersch solution dressings, kept sopping-wet and hot, are of benefit.

10. Forced fluids by mouth, vein, rectum, etc., and attention to the necessary heart therapeusis, is always in order.

11. Hot sitz baths, when ambulatory, stimulates healing, as does ultra-violet light therapy.

I now present for your consideration an analysis of one hundred cases, with the following data:

TABLE 1.—*Mortality: By Age Periods*

Age: Years	No. Cases	Died	Mortality Per Cent
10 and under	2	0	0
10 to 20	3	0	0
20 to 30	8	2	25
30 to 40	13	3	23
40 to 60	31	16	51
60 to 80	42	27	64
80 or over	1	1	100
Total	100	49	49

TABLE 2.—*Duration from History and Findings*

Days	No. Cases	Died	Mortality Per Cent
1	22	3	14
2	25	8	32
3	20	13	65
4	10	6	60
5	8	5	62.5
6	4	3	75
7	4	4	100
8 to 10	6	6	100
10 or over	1	1	100
Total	100	49	49

TABLE 3.—*Type of Operation*

	No. Cases	Died	Mortality Per Cent
Catheter drainage	1	1	100
Incision and drainage	8	6	75
Internal urethrotomy drainage	1	1	100
External urethrotomy drainage	6	3	50
Cystotomy incision drainage	74	28	37.5
Not operated	10	10	100
Total	100	49	......
Bisection scrotum included	21	14	66

TABLE 4.—*End-Results*

Time of Deaths in Postoperative Days	Not Operated 10	Recovered: (Average Stay in Hospital)
On table 1	All died within forty-eight hours	Forty-one days Some remained for other surgery
1 6		
2 to 5 14		
6 to 10 13		
10 or over 5		

TABLE 5.—*Causes of Disease and Location of Extravasation*

	Anterior	Posterior
Carcinoma prostate	5	2
Infection	8	0
Instrumentation	8	0
Fistula	3	0
Stone	2	2
Resection	1	1
Ruptured bladder	0	5
Ruptured urethra trauma	2	2
Stricture	59	0
Total	88	12

SUMMARY

1. After the age of forty years the mortality rate is unbelievably high.
2. Duration of the disease is a very important factor in determining prognosis. The longer in effect the more virulent the infection, the less chance for recovery.
3. Cystotomy, with incision and drainage, seems to be the operation of choice and offers the lowest mortality rate.
4. Bisection of the scrotum seems in some way to detract from chance of recovery, and to add to the mortality rate unless accompanied by other incisional drainage.
5. Every patient with stricture should be taught to return for sounds; and if he does not do so of his own accord, if it were legally possible, a bench warrant should be issued to bring him in at intervals.
6. Every case of extravasation in a teaching hospital should be demonstrated to all internes in a group, so that they would have a better understanding of these cases, not only to diagnose and treat the same, but act to prevent them.
7. Cause of death in order named were septic toxemia, pyelonephritis, cardiac failure; and most all cases were accompanied by degeneration of kidneys, liver, and spleen.
8. Periurethral, scrotal, penile, abdominal, phlegmonous processes may occur without urinary extravasation, and may be entirely bacterial with exudate.

527 West Seventh Street.

DISCUSSION

GEORGE F. SCHENCK, M. D. (1930 Wilshire Boulevard, Los Angeles).—Urinary extravasation is too often overlooked, neglected, or its seriousness not appreciated; and for that reason unnecessary delays and inappropriate treatments are instituted. The condition always demands immediate and radical surgery. The surgery must accomplish, viz., (1) diversion of the stream of urine, and (2) adequate drainage of the involved tissues.

The operation should be done quickly and with the minimum amount of shock because of the patient's general septic and, in many instances, uremic condition. It is usually a poor policy to instrument the urethra at the time of the initial operation.

The advantage of a suprapubic cystotomy is that it simplifies subsequent dilatations of the urethra. However, I see no reason for the drainage to be superior to that obtained via a perineal cystotomy, and the operative shock is less with the latter. A perineal cystotomy is preferable in selected cases. It is the only way to control hemorrhage cases of traumatic rupture of the deep urethra.

Personally, I bisect the scrotum in all cases in which the scrotum is involved. The advantage is that it permits the connecting of all incisions made in the perineum, ischiorectal fossa, penis, groins and prevesical area. It minimizes the gangrenous sluff that is most prevalent within the scrotum. There is no reason for it to increase mortality. However, bisection of the scrotum is by no means a complete operation for urinary extravasation.

⁂

A. A. KUTZMANN, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Negley's concise and comprehensive discussion on urinary extravasation is timely; timely because it falls only to such individuals who have the opportunity of working on a large county hospital urologic service to acquire the necessary experience to diagnose and properly treat this condition. It appears to be a condition more often found in the lower strata of our social order. Many urologists of extensive experience in private practice, seeing very little if any of this type of pathology, often treat urinary extravasation with insufficient boldness. I can only further emphasize the various important points in the paper. The necessity for an early accurate diagnosis is most important, since delay directly increases the mortality. Witness the figures in Table 2 where, from the third day on, the mortality ranges from 65 to 100 per cent. Even early diagnosis may still carry a 20 to 25 per cent mortality in the hands of able urological surgeons. A familiarity with the areas extravasated, as well as the pelvic fascias controlling the spread of such extravasations, will aid the surgeon in localizing the site of rupture. The extravasation, and not its underlying causes (such as urethral stricture, etc.), must then be treated at the moment. The draining of the bladder by cystotomy, and multiple wide incisions of all extravasated or suspiciously extravasated areas is paramount. The latter is most important, for it is here that the surgeon with insufficient experience is apt to be too conservative. If you have a patient with a wide extravasation, be bold and drain most extensively every part of even suspicious appearing areas. I have always made it a point that when I thought that the case had been sufficiently incised, to continue a bit more. It is better to overdrain (if such is possible in some of these cases) than to see your patient die of a progressive toxemia, or to later remove additional areas of necrotic tissue. Of course, cases of localized extravasation, occurring between the layers of the pelvic fascia and confining itself to the scrotum, need only have scrotal drainage; but all others must necessarily be more extensive if you would save your patient. Urinary extravasation cannot and must never be treated conservatively. As Doctor Negley has shown in Table 4, all such patients will die if not drained surgically.

Many of these patients, extravasated over a period of several days, will be brought in moribund and nothing can save them; others treated in a bold manner will make a dramatic recovery, and later advance to a point where the underlying cause of the extravasation may be corrected.

In conclusion, let me stress: (1) early correct diagnosis, (2) extensive and thorough incisional drainage of extravasated areas in conjunction with cystotomy, and (3) correction of the underlying cause of the extravasation in the latter or convalescent stages of your patient.

⁂

H. C. Bumpus, Jr., M. D. (112 North Madison Avenue, Pasadena).—Intelligent treatment of urinary extravasation, following urethral stricture, demands a familiarity by the operator with the fascial planes of the perineum and genitals; for, as the authors have stated, these planes control the advancement of urine escaping from the urethra.

Interesting enough, the principal fascias involved still carry the names of their first describers. Buch's fascia is named for Gordon Buch of the New York Hospital who, in 1848, described the extension of the suspensory ligament of the penis which encloses the penile structures after it fuses with the triangular ligament, and so determines the course of urine escaping from the anterior urethra. Some thirty-seven years prior to Buch's observations, an Irish surgeon, Abraham Colles, had observed that rupture of the posterior urethra was followed by perineal swelling that spread to the scrotum and later to the pubis, while rupture of the deep urethra resulted in abscess formation that pointed in the ischiorectal fossa. He then described what has since been known as Colles's fascia, which, by its density and attachments, definitely limits the extravasation of urine.

The essayists rightly emphasize the importance of early and extensive interference if success is to be expected, and I can but stress the point that, in cases such as they describe, a period of observation has no place. I think it should also be emphasized that stricture in itself is seldom the cause of urinary extravasation. It must be complicated, as in the typical case they refer to, by trauma or infection before extravasation will occur. In fact, it seems very doubtful if true extravasation of urine ever occurs except following trauma. The so-called urinary extravasation associated with stricture is much better termed peri-urethral gangrene, and by thus emphasizing its infectious etiology the hazards incident to neglect of strictures of the urethra are made more apparent.

SARCOID*

By Frederick G. Novy, Jr., M.D.
Oakland

Discussion *by Kendal Frost, M.D., Los Angeles; Nelson S. Keeler, M.D., Oakland; Stuart C. Way, M.D., San Francisco.*

THE recent observation of a patient with sarcoid having an unusual nasal involvement has prompted this short review of the subject and the report of the case. Sarcoids are best considered along with other unusual forms of tuberculosis. While there is by no means complete accord among dermatologists as to the classification of cutaneous tuberculosis, there are in the main three groups:

RELATION OF SARCOID TO OTHER FORMS OF TUBERCULOSIS

1. *True Tuberculosis of the Skin.*—In this group there are two subdivisions: The first is the exogenous type, a direct implantation of the tubercle bacillus into the skin, as exemplified by the anatomical tubercle or tuberculosis verrucosa cutis. The second is the endogenous type, in which the infection is carried to the skin by the blood stream, or direct extension from some deeper tuberculous process, as bone, lymph gland, or excretions from the lungs or gastro-intestinal tract. Examples of this group are: lupus vulgaris, scrofuloderma, and tuberculosis cutis orificialis.

2. *Tuberculids.*—These, because of the association with tuberculosis elsewhere in the body, and their histology, are considered to be due to toxic products of the infection. The most important in this group are lichen scrofulosorum, papulonecrotic tuberculids, and erythema induratum of Bazin.

3. *Sarcoids.*—This includes multiple benign sarcoid (lupoid) of Boeck, sarcoid of Darier-Roussy, lupus pernio, and others which questionably belong here.

RECENT LITERATURE ON SARCOIDS

In recent years the subject of sarcoids has been extensively reviewed by many authors, and the interested reader is referred to such excellent articles as those of Goeckerman,[1] Sulzberger,[2] Nomland,[3] and the recent symposium in France on sarcoids.[4]

DARIER'S FOUR GROUP CLASSIFICATION

Since the first description of this group by Boeck,[5] other conditions have been included. Some of these have stood the test of time, while others have been added only to be again placed elsewhere. The Darier classification, which included four types, has been standard for a long time, and is still used in some texts. These four types were: (1) Multiple benign sarcoid (Boeck); (2) subcutaneous sarcoid (Darier-Roussy); (3) sarcoid nodularis of the extremities; and (4) sarcoid of Spiegler-Fendt.

---

* From the Division of Dermatology, Alameda County Clinic, Oakland, California.

Read before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

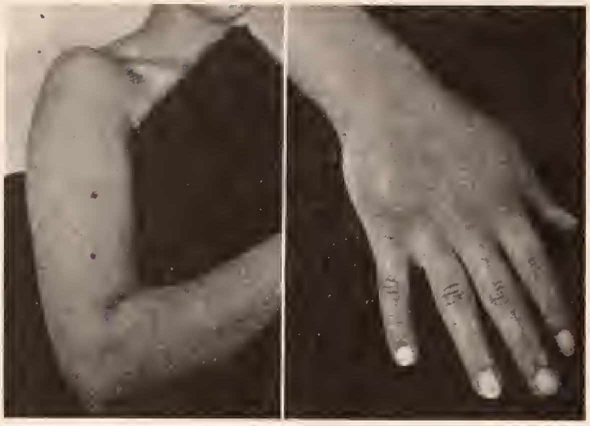

Fig. 1 Fig. 2

Fig. 1.—Superficial sarcoids on the right arm.

Fig. 2.—Sarcoid tumor between the fourth and fifth metacarpals of the right hand.

In a recent communication, Darier[6] no longer includes these last two types. Sarcoid nodularis of the extremities is now thought to be only a form of erythema induratum of Bazin, and so should be placed with it in the group of tuberculids.

OTHER TYPES

Sarcoid of Spiegler-Fendt is a rare neoplastic condition of low malignancy belonging to the group of lymphoblastomas, as has been shown by Sweitzer[7] and Lewis.[8] Clinically, however, there is a close resemblance. The term sarcoid for this condition, because of the confusion, should be discarded, and its other term, sarcomatosis cutis, should be employed.

The difference between the first two types—that of Boeck, and the subcutaneous variety of Darier-Roussy—is really only one of depth of the involvement of the skin. In the latter type, the nodules occur only in the corium or subcutis. Cases showing both types are frequently met with.

Lupus pernio, a condition involving the exposed parts, as the fingers, ears, nose, and feet, with deep colored infiltrations and nodules, should be included, from its clinical and histological picture, in the group of sarcoids. This was the recent general consensus of opinion of European observers.

Nodular tuberculosis of the hypoderm of Wende is another condition, as suggested by Goeckerman,[1] which should not be a separate clinical entity, as it also has the characteristics of sarcoids.

SARCOIDS MAY BE DESCRIBED UNDER ONE HEADING

In brief, then, we may describe sarcoids under one heading. The eruption is made up of scattered papules, nodules, and occasionally plaques involving, for the most part, the face and extremities. These are firm and painless, and when involving the epidermis have a purplish-red color. On diascopic pressure many of the papules have a yellow hue, the so-called, "apple-jelly nodule." The deeper lesions have a tendency to follow the lymphatics and blood vessels. They do not ulcerate or break down. This is an important feature in that other forms of tuberculosis have a tendency to do so. The eruption may appear suddenly, hundreds of lesions appearing in a short period of time, or there may be a gradual evolution, a few nodules developing at a time over a course of years. On healing, either spontaneously or under treatment, there is some atrophic scarring.

Sarcoid is not merely a cutaneous disease, but similar nodules and tumors have been found in nearly every organ in the body. This fact is being recognized more and more, so that now nearly every case reported shows that more than one tissue has become involved. The most frequent of these are the lungs, bones, and mucous membranes.

In the lungs there are rather definite discrete nodules, which usually involve the middle or lower lobes and are around the large bronchi. The x-ray findings are confusing with tuberculosis. The physical findings in the lungs are ordinarily negative. In large series of cases reported recently, as for example, those of Frost,[9] Goeckerman,[1] and Nomland,[3], the percentage of positive lung findings is fairly high.

In the bones, which are also a site of frequent involvement, there are found rather marked changes. In many there is actual punched-out bony destruction and cystic changes. This is seen most frequently in the bones of the hands and feet. Doub and Menagh[10] have reviewed this phase of the subject from the roentgenological viewpoint. This condition has been called osteitis tuberculosa multiplex cystica.

Involvement of the mucous surfaces, such as the eye, tonsils, and larynx have been reported. The nasal mucosa, however, is the most common site. Allison and Mikell[11] reported a case in which there were marked destruction and perforation of the septum, and a tumor mass involving the entire epiglottis. Lomholt[12] states that nearly 60 per cent of the cases seen in Denmark show mucous membrane lesions. He describes three stages in the evolution of the process in the nose. First, there are discrete grayish nodules with an erythematous halo, situated usually on the inferior turbinate. This is similar to the condition seen in the case to be reported, and has not been particularly noted in cases described in this country. The second stage is that of a catarrhal condition with heavy crusts and erosions. The final stage is secondary obstructive hypertrophy of the turbinates and fibrosis.

Enlargement of groups of lymph nodes, particularly those draining areas in which there are cutaneous manifestations, has been noted. Of the internal organs in which sarcoids have been found are the pericardium, kidneys, spleen, liver, and central nervous system.[13]

REACTION TO THE TUBERCULIN TEST

Another finding of interest in these cases is that nearly all of them have a negative tuberculin test. Sulzberger[2] believes this to be due to a condition of anergy in the patient, and is a differential point between this condition and tuberculids which are hyperergic to tuberculin. Martenstein and Jadassohn[14] have shown that serum of

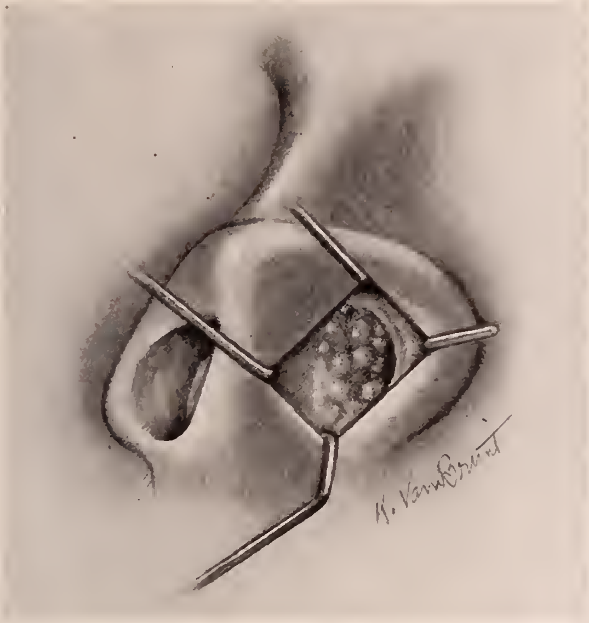

Fig. 3.—Early sarcoid involvement of the nose.

patients with sarcoid, mixed with tuberculin in vitro, gives a negative reaction in susceptible persons. In other words, the serum contains the so-called anticutins which will neutralize the tuberculin, and does not rule out tuberculosis as the etiologic factor.

MICROSCOPIC PATHOLOGY

The microscopic pathology in well developed nodules of sarcoid is characteristic. In early lesions this is not true, in that there is a nonspecific cellular infiltration, mostly of lymphocytes and a few epithelioid cells, about dilated blood vessels. In the well-developed nodule one sees sharply circumscribed tubercles, which are separated from one another by definite connective tissue septa. The tubercles themselves are composed nearly entirely of epithelioid cells, with a slight infiltrate of lymphocytes at the periphery of the nodule. They seem to arise from perivascular tissue. Giant cells are occasionally seen. There is never any evidence of necrosis or caseation, which is a differential point between this and true tuberculosis. In the skin these nodules can be seen in any part of the corium, usually in the deeper portions. Changes in the epidermis are secondary.

ETIOLOGY

The etiology of sarcoid is by no means settled, but today it is thought by most authors to be tuberculous in nature, due to an attenuated or bovine strain of the bacillus. This is substantiated by the many observations of tuberculosis elsewhere in the body at autopsy. Klauder[15] reported such a case. It has been difficult to demonstrate the organism in material from the nodules, and usually animal inoculations have been negative. However, in very early lesions, the bacilli have been found, as in the classical case of Kyrle and that of Wende,[16] if we accept his case as one of sarcoid. In a few instances, inoculated animals, in this very early period, have also been positive for tuberculosis.

There are, however, many who think that the sarcoid reaction is not typical for any specific disease, but can be caused by several other different infections, as syphilis, leprosy, and even foreign bodies if the tissue reaction of the individual is such as to produce this type of response. Darier[6] recently felt this way as to the etiology.

A third group feel that sarcoid is a disease by itself, as it is a generalized reaction involving not only the skin, but usually other organs at the same time. The negative tuberculin reaction is to them against a tuberculous etiology, as well as the nearly negative results of finding the bacillus of tuberculosis, either directly or by animal inoculation. Another point brought out is the peculiar bone and lung findings. These, however, could well be on a tubercular basis.

At present, the bulk of positive evidence is that sarcoids are a manifestation of tuberculosis.

REPORT OF CASE

Case 1.—W. M., a colored school girl, age seventeen, was first seen at the Oakland Health Center, May 22, 1934, complaining of frequent nosebleeds and an eruption on the arm of several months' duration.

In December, 1933, the patient had a "bad cold," and at this time she had an infected finger which took some time to heal. The cold persisted, and with it she began to have nosebleeds and some discharge which formed heavy crusts. These symptoms became more and more noticeable, so that obstruction of the nose developed at times and she would have trouble breathing. This continued until the time of her first visit.

In February, 1934, she had an infected area on the right leg which cleared up in about three weeks, with a slight scar. About the same time two small nodules appeared, one on the right arm, and the other on the chin. For some time these gradually grew larger, and then remained stationary. There was no pain associated with their development, but they were somewhat tender to touch. After some weeks of evolution the involved skin took on a purplish color, and later there was some slight scaling. This was in March, 1934. Since that time there has been no change in their appearance. Other new lesions have developed recently. Several on the back of a similar nature, and others which she could feel, but which showed no change in the overlying skin.

In May, 1934, a painless swelling developed in the right hand which gradually increased in size. At first there was no interference in motion, but of late there has been some.

Along with the above conditions she has had some general malaise. From April to July there has been a loss of ten pounds in weight. Recently there have been frontal headaches, which have increased in frequency and severity. After eating she has felt distended, and occasionally there has been vomiting.

The past and family history were negative. There have been no known contacts with tuberculosis.

Examination. — The patient was first seen in the otology service, and at this time she presented hypertrophy of the septum and turbinates, with a purulent discharge. This condition did not change.

On July 13, 1934, she was seen in the dermatologic clinic and presented about twenty scattered nodules over the face, extremities, and trunk. These varied in size from about one centimeter to three centimeters in diameter. They were all firm and nonlobulated, and not tender to palpation. Most of them did not involve the epidermis, nor did they appear to be attached to it. On the outer aspect of the left arm were two tumors, one above the other, which had the same consistency, but they definitely involved the overlying epidermis. The skin had a deep purplish hue and in the center part of these there was some crusting which, on removal, showed a serous discharge, but no ulceration. On diascopic pressure there was a suggestion of a yellowish nodule, but this was not definite. The chin and back presented similar lesions. All of the others, as stated above, were subcutaneous.

The right hand presented a tumor mass between the fourth and fifth metacarpals. This was irregular, slightly movable, and of a nearly bony consistency, and appeared to be attached to the bone. Biopsy from this mass was taken several months later by Dr. L. Barnard, who found the tumor to be attached to the tendon, and not to involve the bone.

The mucous membrane of the nose presented marked crusting which, on removal, showed considerable erythema. Scattered over the septum, lateral wall, and floor of the nose, there were numerous pearly discrete tumors resembling small buds of granulation tissue. They were about the size of a glass-headed pin. The rest of the pharyngeal mucous membrane was normal. Bronchoscopic examination showed no evidence of lesions in the bronchial tree. Two of these tumors were removed by Doctor Keeler, one for histologic study, and the other for guinea-pig inoculation. General examination did not reveal any other pathology.

The routine laboratory tests of the urine and blood were negative, except that there was a slight secondary anemia. The sputum did not show any acid-fast organisms. The culture from the nose did not have any unusual organisms.

The guinea-pig, inoculated with one of the tumors from the nose, was killed and autopsied at the end of two months. No evidence of tuberculosis was found. This finding is frequently met with in cases of sarcoid. Only very early lesions have showed positive inoculations.

Intracutaneous injections of old tuberculin were negative with 0.1 milligram and 1.0 milligram.

X-ray findings of the hands and feet did not show changes so commonly seen in this condition. This was a little surprising, in that the patient had this hard swelling in the right hand. An x-ray of the lungs showed only slight bronchial thickening, and none of the nodules which have been noted in some of these cases.

Biopsies. — A biopsy was taken from one of the papules on the arm and examined in the dermatology department of the University of California. The epidermis showed elongation of the rete pegs, and in the basal layers there was some intercellular edema. The granular layer and outer layers were normal. Throughout the corium there was some edema. This was particularly noted in the papillary bodies. There was a slight cellular infiltration, which was made up mostly of lymphocytes which tended to be perivascular. Deep in the corium there were several well-formed tubercles. The largest of these extended down nearly to the fatty layer. They were made up of a dense collection of epithelioid cells and fibroblasts. At the periphery of the tubercle there were a few lymphocytes. No giant cells were noticed. There was no evidence of central necrosis.

In the upper corium, divided by connective tissue septa, were several small early tubercles similar to the larger deeper ones. The cytoplasm of some of the epithelioid cells was stained poorly, and there was a tendency for vascuolization.

The biopsy from the nose had a transitional type of epithelium, but a few goblet-cells were seen. Throughout the section there were several large granulomas which were discrete, and extended as deep as the section of the skin. At the margin the fibroblasts were greater in number and seemed to form nearly a limiting membrane. No giant cells and no necrosis were noticed. A number of the tubercles were rather vascular, and large blood vessels could be noted in the central part. There was an infiltrate of lymphocytes which was confined almost entirely to the periphery, but when blood vessels were present they would tend to follow them into the central part of the tubercle. In the dense tubercles this vascularization was not noted. Throughout the section there was some lymphocytic infiltration about the mucous glands.

The section taken from the tumor of the hand presented the same pathology as the other two biopsies. There was no evidence of bony involvement.

The histopathologic diagnosis was that of sarcoid.

The patient has recently completed a course of six injections of neoarsphenamin with no change in the lesions except the tumor on the hand, which has become larger.

COMMENT

The laboratory findings in the case herein reported are similar to those found in most cases of sarcoid, namely, a negative reaction to tuberculin and no evidence of tuberculosis in a guinea-pig inoculated with one of the tumors.

The lungs and bones, frequent sites of infection, were free of evidence of the disease. This is somewhat surprising in the case of the bones of the right hand, as the tendon sheath between the fourth and fifth metacarpals was markedly involved.

The unusual features of this case were that the patient presented nodules of the skin, both of the superficial and deep types, and similar lesions in the nose. While nasal involvement is by no means rare, the type seen in this case, of small discrete pearly nodules, is apparently unusual in this country.

DISCUSSION

Kendal Frost, M. D. (1930 Wilshire Boulevard, Los Angeles).—The group of conditions to which we give the name of sarcoid has interested me for a number of years. Doctor Novy's presentation of the tuberculous aspect of the condition is so adequate that it needs no further elucidation. There is a school in Denmark, particularly, which believes that sarcoid (both Boeck and Darier-Roussy types) is due to a bacillus closely allied to the tubercle bacillus, and also resembling in some ways the bacillus of leprosy. Kissmeyer has written an excellent monograph on the subject of sarcoids in which this idea is developed. He draws a distinct line between the tuberculids, including lupus pernio and the sarcoids which, according to their thesis, are a separate entity produced by a specific microörganism, responsible for the skin lesions as well as the bone and pulmonary and other visceral findings. Denmark is one of the localities in which there is relatively high incidence of the disease. In North America the disease is among the rarities. It seems reasonable to not entirely disregard this opinion coming from a locality in which a rich material is available.

* * *

Nelson S. Keeler, M. D. (411 Thirtieth Street, Oakland).—From the standpoint of the rhinologist, sarcoid changes in the nasal mucosa appear to be an extremely rare finding. This is the first case which has come under my observation, and numerous inquiries among others in the same field have failed to reveal any other experience with it.

The most striking characteristic of the lesions in this case has been their tendency to persist without any change. Examination of the nose now presents the same picture as the original drawing, made eight months ago, the tumors retaining their discrete, pearly appearance, and remaining the same size.

A differential diagnosis should include tuberculosis, glanders, leprosy, and syphilis. The former three may be seen in their earlier stages as granulation nodules, in which, of course, may be found the causative bacteria.

* * *

Stuart C. Way, M. D. (490 Post Street, San Francisco).—Doctor Novy, in a commendable manner, has briefly summarized our present knowledge on the subject of sarcoid. This disease, common on the European continent, is somewhat of a rarity in California.

With due respect to the recent and accepted changes made in its classification, differences of opinion persist because of the disputed etiology.

While many observers are in accord that sarcoid is a tuberculous manifestation, it seems reasonable to assume that its pathology, as is the case in other diseases, is capable of being produced by more than one bacterial toxin.

Sutton's statement that arsenic appears to be a specific in the Boeck and Spiegler-Fendt type of sarcoid speaks in behalf of its nontuberculous nature.

Although the Spiegler-Fendt type is no longer classified among the sarcoids, it is probable, as Fox and Wile have indicated, that many cases of sarcoma of the skin supposed to have been cured by arsenic really belong to the sarcoid group.

E. Hoffmann, in 1925, discussed an unusual case resembling lupus pernio, and the x-ray plates shown clearly demonstrated the presence of cystic degenerative changes in the long bones of the hand. Since that date, numerous cases of lupus and sarcoid have been personally examined for osteitis tuberculosa multiplex cystica, with negative findings. Therefore, the conclusions reached were that it is a rare complication, and not common, as Doctor Novy believes.

THE LIVER AND CARBOHYDRATE METABOLISM[*]

By Douglas R. Drury, M.D.
Los Angeles

Discussion *by Alvin G. Foord, M. D., Pasadena; Fred H. Kruse, M. D., San Francisco.*

In the limited space of a short article, one can treat adequately only one or two sections of the large field embraced by this subject. The liver is the real center of carbohydrate metabolism, by virtue of its control of the blood sugar level. This "duty" alone embraces many important processes. We must consider, besides, the bearing of these processes on the other activities of the liver, and it is with some of these relationships that I shall deal here; in other words, how is the liver affected by its activities in carbohydrate metabolism?

SUGAR AND FAT METABOLISMS OF THE LIVER

The relationship of the sugar and fat metabolisms of the liver is an interesting one. When the liver is storing glycogen, the fat content diminishes, as a rule, and vice versa. This reciprocal activity has been called the fat-glycogen antagonism of the liver. There are many circumstances under which fat will accumulate in this organ.

During fasting the liver becomes fatty, and this is very readily counteracted by sugar administration. In diabetes the liver fat tends to increase and this is prevented by increasing carbohydrate metabolism, often, of course, with the aid of insulin. When fat alone is fed to an animal the liver lipoid increases; but if carbohydrates are ingested at the same time the liver does not retain the fat which must be deposited elsewhere. Table 1, taken from the work of Rosenfeld, clearly illustrates this. It shows the results of feeding sesame oil to two groups of dogs. The first group received 30 grams of oil per kilo for four days; the second group received, besides the same dose of oil, 8 grams sugar per kilo.

Table 1.—*Showing Results of Feeding Sesame Oil to Two Groups of Dogs*

Dog Group	Liver Fat in Per Cent	Average
No. 1	27.1, 36.2, 26.8, 24.7	28.7
No. 2	15.5, 13.9, 6.8, 12.9	12.3

It is quite apparent that the added sugar prevents the deposition of fat in the second group of animals.

This antagonism can be demonstrated in still another way. If the amount of liver tissue in an animal be greatly reduced by excision of a large part of the organ, the remaining fragment will become markedly infiltrated with fat. Two-thirds of the liver of the white rat can be removed, with recovery of the animal. If an ordinary diet of

bread and milk be given these animals, we find the fat content of the surviving lobes of the liver greatly increased after one day, and it remains high for four to six days. If glucose be administered to the animals by adequate repeated injections, the fat influx can be prevented. Table 2 illustrates this action.

This shows how reduction of the amount of liver tissue results in a marked influx of fat in the remaining part, and how this may be prevented by the injection of proper amounts of glucose. These results are of practical interest, because, although we do not remove large amounts of the liver in patients, there are many diseased conditions and toxic agents which cause a marked reduction in functioning liver tissue, and we might well assume this tendency for fatty infiltration will obtain here, as in experimental animals, and also, that it may be combated with adequate carbohydrate administration.

These instances indicate the effectiveness of sugar in controlling fat deposition by the liver. It might be well to indicate next the practical significance of this action.

SUSCEPTIBILITY OF THE LIVER TO TOXIC AGENTS

It is now a well established fact that an increased concentration of fat in the liver greatly intensifies the susceptibility of this organ to toxic agents. The early work of Rosenfeld, of Whipple, and of Graham first established this fact, and many experimenters since have confirmed it. Agents that will cause necrosis of the liver cells, which contain fat, fail to do so if the fat has been kept out by previous carbohydrate administration.

A similar action is illustrated in Table 3. This shows the results of an experiment on a group of rats that had been given a rich cream diet prior to removal of two-thirds of the liver. Ordinarily this operation has a zero mortality—that is, for animals that have been fed previously on a bread-and-milk diet. In this case four out of eleven animals, or 36 per cent, died during the first twenty-four hours after operation. It is of interest to note that the four that died were those having the highest concentrations of fat in the liver at the time of operation.

One of the most noteworthy characteristics of the liver cell is its remarkable capacity for regeneration. Large portions of the liver substance may be eliminated by experimental surgery, or by toxic agents with complete functional recovery in a few weeks. Patients who have survived a severe acute yellow atrophy, and have been examined later, have shown liver tissue normal in amount and quality. This characteristic of the liver can be quantitatively studied in the white rat. Two-thirds of the liver is removed surgically in a large number of these animals, and the rate at which the remaining tissue grows back can be followed by sacrificing groups of them after varying periods of recovery, and determining the number of liver cells in the surviving organ. The number of cells in a liver may be quite accurately estimated by counting the cuboidal-cell nuclei in small samples of unit volume, and multiplying this number by the volume of the entire liver. The liver of the 150-gram white rat contains about 600 million so-called cuboidal cells. Chart 1 illustrates the rate at which the number of cells of the remnant is reëstablished after removal of two-thirds of the organ. This chart illustrates the advantages of determining cell number rather than liver mass. The broken line indicates the weight of the surviving organ, the unbroken line the number of cells, all expressed in terms of percentage of the normal or preoperative value. From the first to the fourth day the weight of the organ is unduly high because of the influx of fat and other substances, which do not represent functioning tissue but may be actually obstructive and harmful. Be-

tween the fourth and sixth days the weight actually diminishes due to the removal of fat. The number of cells, on the other hand, begins to augment at the second day and continues to increase steadily, though at a diminishing rate in a curve that is logarithmic in character. Table 4 illustrates the effect of a high fat diet on this regenerative process. It shows also the necessity of counting cells rather than taking the weight of the tissue. The weight figures give a false impression of growth, since much of this increased mass is due to the influx of fat. The cell count, on the other hand, shows a definite retardation in the regenerative process—a process that is of great importance to the body in recovering from disease involving the liver.

KETOSIS PRODUCTION BY THE LIVER

There is still another process of the liver in which fat and carbohydrate are involved: that is, in the production of ketosis. That ketone bodies can be produced by the liver was first shown by Embden in perfusion experiments. The work of Chaikoff and Soskin points to the liver as the main site, if not the sole site of the formation of these substances. Essentially, their findings were that acetone bodies disappeared quite promptly from the blood and tissues of the diabetic dog, when the liver was removed. The kidneys had been excised to prevent loss through them. Some recent work in our laboratory has lent support to their conclusions. A human subject was placed on a ketogenic diet, which was kept rigidly constant for three weeks. Thus with the caloric intake steady, the metabolism was varied from day to day by varying the amount of exercise carried out by the subject. From Table 5 we can see that the output of ketone bodies is not increased on the exercise days. The highest ketone excretion actually occurred on a day when the subject remained in bed for the entire twenty-four hours. The concentration of ketone bodies in the blood was a maximum on this day. The source of energy for the muscles during these exercise days must have been predominantly fat, since that was the character of the diet throughout. This increased metabolism of fat by the muscles does not increase the ketone body production. This fits in with the conclusion of Chaikoff and Soskin, that appearance of ketone bodies in excessive amounts in tissue fluids is due to increased rate of production by the liver. This activity of the liver is very definitely influenced by carbohydrate metabolism of the individual. Increased utilization of sugar by the subject leads very promptly to a diminished production of ketone bodies by the liver. Insulin may be an important intermediary agent in this process. Here again we have a very definite reason for the administration of carbohydrates, possibly in some cases with the addition of insulin, to cases that might be threatened with ketosis and its baneful results—acidosis and dehydration.

University of Southern California.

DISCUSSION

ALVIN G. FOORD, M. D. (Pasadena Hospital, Pasadena).—Doctor Drury's interesting findings concerning the reciprocal deposition of fat and glycogen in the liver should be of considerable clinical importance. Several years ago, for instance, Le Count published reports of a series of patients having chronic alcoholism, who died suddenly with symptoms and laboratory findings of marked hypoglycemia, and in whom at postmortem the only important finding was a marked fatty infiltration of the liver. He believed that the disturbance in sugar metabolism was due to the profound filling of the liver cells with fat to such an extent that they were not able to convert glucose into glycogen and maintain the normal blood-sugar level. The view by some that the alcoholic tremor and the profuse sweating of advanced alcoholism are due to hypoglycemia is strengthened by Le Count's observations, and also by the present studies of Doctor Drury. Thorough blood chemical studies should be made on this group of patients in the light of known facts, and also postmortem studies of the liver to determine the rôle played by fat in the liver of these patients.

*

FRED H. KRUSE, M.D. (384 Post Street, San Francisco).—Clinicians have realized for many years the importance of the liver as a storehouse for glycogen which, in turn, maintains the proper blood-sugar levels. They have also known that the glycogen store is depleted in obstructive jaundice and other disorders of the liver and, in the last several years, the feeding of sugars and other carbohydrates, and the intravenous administration of glucose have become a recognized procedure preliminary to all biliary-tract surgery and the chief therapeutic aid in the treatment of the cirrhoses and degenerative changes in the hepatic parenchyma. It has also been generally recognized that in obstructive jaundice especially, and presumably in the more diffuse changes of toxic and degenerative hepatitis, the protein metabolism of the liver has become deficient, so that a low protein intake must be assured to prevent ascites and edema.

As demonstrated so clearly in the experiments of Doctor Drury, the relationship of the sugar and fat metabolism of the liver, and that injurious fat accumulations develop as the glycogen content lessens, has not been widely known. The appreciation of this reciprocal activity, the fat-glycogen antagonism, is evidently of the utmost importance for practical therapeutic purposes, not only in the treatment of diabetes, ketogenic and acidosis states, acute diarrheic and depleting gastro-intestinal upsets, but also in the essential liver disorders mentioned above.

Heretofore, in biliary diseases associated with jaundice, the clinician has usually prescribed a fat-free diet because the absence of bile in the duodenum has prevented the proper emulsification or saponification of fats with consequent intestinal derangements.

Apparently much is yet to be learned of the lipoid metabolism of the liver. In obstructive jaundice there is usually hypercholesteremia, which roughly parallels the degree of obstruction and bilirubinemia. In cases of degenerative diseases of the liver, the greater the damage to the liver the greater the hypocholesteremia which accompanies the hyperbilirubinemia.

It is also known that marked thyrotoxicosis produces extensive hepatic necrosis, and it also produces hepatic glycopenia. As already stated by Doctor Drury, livers with low glycogen content have an increased susceptibility to injury, and they also accumulate fat.

It would appear, therefore, that the amount of fat ingestion by the alimentary canal, if it can be adequately handled by the gastro-intestinal tract, is not of such primary importance in the effect on the liver if there is an adequate carbohydrate intake which insures repletion of the liver glycogen.

The same accumulation of fat in the liver may take place by robbing the tissue stores even on a fat-free diet, due to the general metabolic disturbance, unless prevented by the provision of more liver glycogen.

It may be pertinent to mention here, also, that conditions which produce anoxemia—such as congestive heart failure, pulmonary infarcts, severe anemia, pulmonary consolidation (lobar pneumonia), and other conditions—produce liver damage by lowering the glycogen stores and increasing the fat accumulations, and require increased carbohydrate therapy.

CAUDAL AND TRANSSACRAL ANESTHESIA*

By Clark M. Johnson, M.D.
San Francisco

Discussion *by Frank Hinman, M.D., San Francisco; A. M. Meads, M.D., Oakland; Charles F. McCuskey, M.D., Los Angeles.*

THE purpose of this discussion is to remind anesthetists and surgeons of some of the advantages of regional anesthesia in general by restating our experience with one type, namely, caudal and transsacral block. Any of the desired spinal nerves may be reached by paravertebral, cervical, dorsal, lumbar, or transsacral and caudal injections. Although the latter is the only type with which I have had experience, the indications and advantages are comparable in all types of regional anesthesia once the technique is mastered, and its limitations are understood by the surgeon. There are three reasons why regional anesthesia has been so little used on the Pacific Coast. First, most surgeons are satisfied with the great advances made in general anesthesia, and with the occasional use of spinal anesthesia. Second, few anesthetists have troubled themselves to master the rather simple technique, and hence it has not been available. Third, some anesthetists and surgeons are unaware of the advantages of regional anesthesia in certain cases. No surgeon of wide experience limits himself to the use of any one anesthetic. He realizes that the anesthetic must be fitted to the patient, not the patient to the anesthetic. The wider his experience and that of his anesthetist, the more varied will be his selection. Many surgeons have recognized the advantages of regional anesthesia in certain cases, and have given the injections themselves with excellent results. Others have started and then abandoned the method because it is a rather fussy and time-consuming procedure. Although we have persisted in giving our own transsacral and caudal blocks for ten years, we recognize that it is primarily the anesthetist's work. It requires the presence of an anesthetist during the operation to watch the patient, and to give additional anesthesia if required. For the method to be successful, it requires close coöperation with the surgeon who must understand the advantages as well as the limitations. The anesthetist must also know beforehand the type and extent of the operation which is to be performed.

REGIONAL ANESTHESIA

The perfect anesthetic for all patients and for all operations, and one which does not affect any of the vital processes, which can be used with equal impunity in the infant, the robust youth, the ancient and feeble arteriosclerotic person, the septic patient or the one in shock, has not yet been discovered. Until we have such an anesthetic available, I am convinced that regional anesthesia is definitely indicated in certain cases. This opinion is based upon the use of caudal and transsacral anesthesia for over nine hundred urologic procedures (Table 1) on the urologic service at the University of California.

CONFUSION IN TERMINOLOGY

Considerable confusion exists in the terminology. Caudal block (incorrectly called sacral) consists merely in inserting a needle through the sacral hiatus into the sacral canal, and there de-

* Read before the Anesthesiology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13 to 16, 1935.

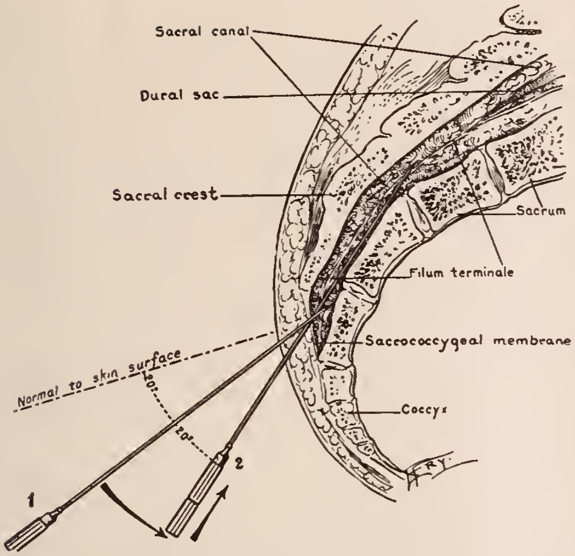

Fig. 1.—Shows the insertion of needle through the sacral hiatus and advanced into the sacral canal where 30 c.c. of procaine is deposited for caudal block. (After Labat, 1924.)

positing the anesthetic solution (Fig. 1). This reaches the third, fourth and fifth sacral nerves and the coccygeal plexus. Transsacral block is performed by inserting a needle through each of the sacral foramina on both sides and depositing the solution directly about the nerves (Fig. 2). When this is done it is usually accompanied by a caudal block, which insures prolonged and complete anesthesia of all five sacral nerves and the coccygeal plexus.

CAUDAL BLOCK

Caudal block alone is ideal for the following procedures: (1) Cystoscopic manipulations in badly inflamed (tuberculous especially) or contracted bladders, fulguration of tumors or ulcers of the bladder, crushing and removing stones. (2) Catheters or other instruments can often be passed after caudal anesthesia in difficult cases when such passage has been impossible before anesthesia. Many patients with acute retention have been spared a cystotomy in this manner. (3) Incisions in the male or female perineum are painlessly made, and hemorrhoidectomy can be performed. (4) Lastly—and most important at the present, especially from the urologist's standpoint—caudal block is ideal for transurethral resection. It has many advantages in this procedure. There is no straining, there is good relaxation, there is less troublesome bleeding, and the anesthesia lasts at least one hour, and usually an hour and a half. The electric spark may be used without fear of explosion. There is also this advantage: under caudal anesthesia, overdistention of the bladder is painful. This fact serves to prevent some of the accidents that occur under general anesthesia.

COMBINATION OF CAUDAL AND TRANSSACRAL BLOCK

A combination of caudal and transsacral block gives a more extensive anesthesia, permitting perineal prostatectomy, and extensive operations on the lower rectum, female perineum, vagina, and cervix.

Advantages. — Some of the advantages have been mentioned. I can best sum them all up by saying, first, that we have used this method in over nine hundred cases and have never had a death attributable in any way to the anesthetic, and second, that over three hundred of these injections were for perineal prostatectomies. Perhaps the last statement should be amplified. Where can you find a group of patients who are older, more feeble, more arteriosclerotic, who have poorer hearts and kidneys than a group of patients with prostatism? It has rarely been necessary to refuse to operate on any patient, clinic or private, regardless of cardiac or other complications, such confidence have we developed in this anesthesia for perineal prostatectomy. The reasons are obvious. There is little or no change in blood pressure, no nausea or vomiting, no inhibition of kidney function; there is good relaxation and prolonged anesthesia (from one and one-half to two hours usually) which permits of good exposure and plenty of time when necessary to secure perfect hemostasis. There is no postoperative headache or nausea, and patients can be given fluids freely by mouth. I am conscious of the fact that there are many who believe that a low spinal block is easier and gives equally good results. That it is easier, I agree. It has not been our experience that it is equally safe for all patients. For the patient who is an average or even fair risk, spinal block is perhaps as satisfactory as regional anesthesia, but not for the very aged and those who are poor risks, especially those with marked myocardial damage. Because it is so benign for such patients, we feel that it is advantageous for those who are in fair or even very good condition. We reserve spinal anesthesia for use in radical prostatectomy, for carcinoma, and for surgery on the bladder and lower ureters. These conclusions were reached after a fair trial of spinal anesthesia in over two hundred cases.

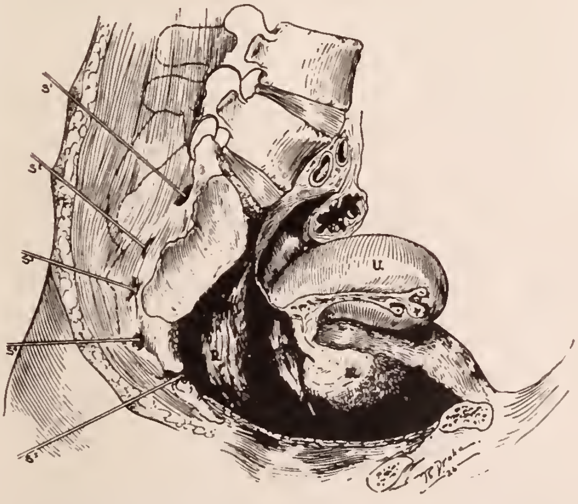

Fig. 2—Sagittal section of sacrum showing the location of the sacral foramina and the direction in which the needles are advanced to reach the sacral nerves in transsacral block. (After Labat, 1924.)

Disadvantages.—The so-called nervous patient who cannot be operated upon when awake exists chiefly in the minds of the patients and physicians themselves. The patient who has confidence enough in a surgeon to be operated upon, if properly approached, will allow him to select the anesthetic. This requires, however, the confidence of the surgeon and the anesthetist in the method. That it is sometimes a fussy, time-consuming method, is admitted. If, however, it is safer, this objection should not be considered.

Failures.—The possibility of failure to obtain anesthesia is a disadvantage. Failures are caused either by faulty technique, or poor coöperation and roughness, or a more extensive operation than was planned by the surgeon. In our first series of 270 cases, reported in 1929,[1] there were eight partial failures, three requiring other anesthesia, and one complete failure. Our percentage has been about the same since. In several instances, abnormalities or pathologic changes in the sacrum have made the injection impossible.

Reactions.—Though reactions from procain are not common, they do occur and, while they may be startling for a few moments, none has proved fatal. Most reactions can be prevented. The use of sodium luminal and caffein intravenously has proved the best restorative in our hands. In addition, the head should be lowered.

TECHNIQUE

It would be superfluous to attempt to give in detail the mechanical technique, as it was well described years ago. We have followed closely the technique of Gaston Labat,[2] with minor changes. Although any form of nerve block is relatively simple, it requires a definite understanding of the anatomy involved, especially the landmarks used to reach the desired nerves as well as the anesthesia that will result. With this knowledge and a few trial injections on a cadaver, using methylene blue so that subsequent dissection will show any errors, the technique is readily acquired. Hit or miss injections are doomed to failure in the majority of cases. Experience has taught us that certain details are as important as the technique of injection itself.

The following routine is used:

1. The patient may have fluids until one-half hour before the injection. Breakfast is not withheld except for major surgical procedures (prostatectomy).

2. Barbital, grains 10, is given the night before and again the morning of the operation. Most of the barbiturates in equivalent doses are satisfactory. Barbiturates are essential to prevent reactions and are helpful in calming the patient. A small dose of morphin also may be given before major surgical procedures. Scopolamin has been extremely unsatisfactory in our experience and, in fact, is definitely contraindicated.

3. Needles must be sharp and straight, and should be handled gently. No injections should be made without first aspirating and, if blood is withdrawn, the needle must either be removed and replaced or moved far enough so that there is no more bleeding before injecting.

4. Thirty cubic centimeters of fresh, sterile solution of procain (two per cent) is injected into the sacral canal when the caudal block is done alone. For the combined caudal and transsacral block, 30 cubic centimeters of one per cent solution of procain is put in the sacral canal and 10, 8, 6 and 4 cubic centimeters, respectively, in the first, second, third, and fourth sacral foramina. One hundred cubic centimeters of one per cent solution is the maximum that should ever be used, and the amount should be decreased, according to the weight, age, and general condition of the patient.

5. Twenty minutes should elapse after simple caudal injection before starting the operation. When the transsacral block is used, anesthesia will be complete, as a rule, as soon as all of the foramina have been injected.

6. The anesthesia should be tested by pinching the perineum with a small hemostat without warning the patient, but simply watching his facial expression. The patient should never be asked "does this hurt?" It puts him on edge and makes him feel that the surgeon is not sure that he will not be hurt when the operation begins. I have never known a patient to remain silent if the anesthesia were poor.

7. The patient should be kept flat, or in a slight Trendelenburg position for four hours after transsacral block.

CONCLUSIONS

1. Our experience with caudal and transsacral anesthesia has led us to believe that this method, as well as other methods of regional anesthesia, is not only suitable for many surgical procedures but definitely indicated for patients who are bad risks.

2. These methods would be in more general use, and the results would be better if these injections for regional anesthesia were done by anesthetists who would take the pains to become proficient in the technique.

DISCUSSION

Frank Hinman, M. D. (603 Fitzhugh Building, San Francisco).—The discussion by Doctor Johnson of caudal and transsacral anesthesia is very good, and I agree with him fully as to the indications of use of these methods of anesthesia.

Nearly all my recent anesthetics in private practice have been given by Doctor Johnson. There has been practically 100 per cent success of the anesthesia when the transsacral method has been used, but there have been a number of failures with simple caudal anesthesia; so much so that I am inclined to discard its use altogether. It is a great disappointment to both the patient and surgeon to find, after caudal needling, that no anesthesia has been obtained.

This is the sole objection to caudal anesthesia. If it always worked, it would be the ideal anesthetic for conditions mentioned by Doctor Johnson. In cases of perineal operations which require an hour or longer, the transsacral anesthetic, as a rule, wears off, so that it needs to be reinforced with gas and oxygen. There is, of course, no real objection to this, because a minimum of gas and oxygen may be used. Recently, the use of procain and nupracain has secured a much longer anesthesia than procain alone.

Transsacral anesthesia is the ideal one for perineal prostatectomy.

*

A. M. Meads, M. D. (251 Moss Avenue, Oakland.—Doctor Johnson's paper on caudal and transsacral anesthesia gives us an excellent review of the subject, and of his personal experience. There is no doubt that this type of anesthetic, from the urologic point of view, can be most satisfactory where surgery of the bladder and of the prostate are concerned. However, there are certain drawbacks in its practical application which have made me, although once enthusiastic about it, rarely use it now.

Some years ago, on visiting the Mayo Clinic, I found that practically all operations on the lower urinary tract were carried out under caudal and transsacral anesthesia, the anesthetic being administered by a trained anesthetist with about 20 per cent failures. A year ago, however, on visiting the Mayo Clinic again, I found that on the urological service caudal and transsacral anesthesia had been entirely replaced by spinal anesthesia; not because the former was not satisfactory, but because spinal anesthesia gave equally good results, with no more mortality or severe reactions. Furthermore, the percentage of failures from spinal anesthesia was decidedly less than that with the caudal and transsacral anesthesia, and the area anesthetized was so much greater that the use of local anesthesia in the suprapubic area was unnecessary.

My personal experience with this type of anesthesia began some years ago, and my results in the first few instances were so satisfactory that I grew enthusiastic. Then one of my cases developed a convulsion on the table during the injection of the novocain solution into the sacral canal, causing me considerable anxiety. Later we had failures in several of our private cases, which were extremely annoying both to the patients and to me. We also found the technique difficult and time-consuming, as we had no anesthetist trained in this method.

On taking up spinal anesthesia again, we found that we saved much time thereby, had far fewer failures, and no more serious reactions than when we were using caudal and transsacral anesthesia.

Caudal and transsacral anesthesia will probably never be popular except in institutions where trained anesthetists can administer it and have the patient ready for the operator at a given time. However, as Doctor Johnson has said, when once administered properly, there is no better anesthetic in selected cases.

*

Charles F. McCuskey, M. D. (2439 North Commonwealth Avenue, Los Angeles). — The factors influencing the selection of an anesthetic agent or method vary according to the individual patient and surrounding circumstances. Too frequently the ultimate selection is determined by the inability of the attending anesthetist to produce satisfactory anesthesia of the type indicated. When a surgeon or anesthetist allows this situation to arise, they are relegating the welfare of the patient to a position of minor importance. The type of anesthetic used on each case should be given the same consideration as the type of operation contemplated, taking into consideration at all times the patient's comfort and safety during and after the surgical procedure.

The success of regional anesthetic procedures is dependent upon the skill of the anesthetist in producing anesthesia with a minimal amount of pain. Unlike general anesthesia, the patient is capable of judging the success or failure of the procedure. When the site of operation is limited to the area inervated by the sacral nerves, it is very unusual to find a patient postoperatively who has not been pleased with the anesthetic procedure. In a series of over eight thousand operations performed under caudal and transsacral block anesthesia administered by my associates or myself, approximately 95 per cent had satisfactory anesthesia. For operations on the rectum, excluding posterior resections, better than 99 per cent successful anesthesia can be obtained.

Untoward reactions to procain may be due to an intravenous injection or to a rapid absorption of the solution. An intravenous injection of procain is characterized by temporary loss of consciousness, with or without convulsions, respiratory depression or paralysis, and slowing of the pulse rate to forty or less beats per minute, the degree of these symptoms depending on the amount of solution injected.

Symptoms due to rapid absorption of the procain come on slowly and are characterized by pallor, nausea with or without vomiting, slowing of the pulse rate, and the usual appearance of shock.

The administration of oxygen and carbon dioxid is usually sufficient to overcome these symptoms. If sufficient procain has been injected to paralyze respiration, this must be done promptly by artificial respiration until normal respiration is restored. Procain is broken down in the liver to one of the acids of the paramino group and then eliminated through the kidneys. For the milder type of reaction, the administration of caffein sodium benzoate or adrenalin may be sufficient. Severe untoward reactions are very uncommon and the milder type occur in less than 0.5 per cent.

RUPTURED APPENDIX IN CHILDREN: ITS MANAGEMENT*

By Conrad J. Baumgartner, M.D.
Los Angeles

Discussion *by William J. Norris, M.D., Los Angeles; Ezra S. Fish, M.D., Beverly Hills; George Thomason, M.D., Los Angeles.*

THE subject of appendicitis, though admittedly well worn, continues to present many serious and important features; particularly so when dealing with children. It is obvious that the public at large, and physicians to no small degree, are as yet not aware of the possible seriousness of the average so-called "stomach ache" in children. In a recent series of one hundred consecutive operated cases of appendicitis in children, occurring at the Children's Hospital, we find an appalling number ruptured, namely, 55 per cent, eight of whom had a generalized peritonitis which proved fatal in five. The explanation lies simply in the failure of parents and, at times, physicians to appreciate early the danger that might exist in the simple complaint of the child, of "pain in the abdomen."

In the series mentioned twenty-five, or almost half, were not admitted to the hospital until after the fourth day, and only three came in within the first twenty-four-hour period; while of the thirty-six acute cases that had not gone on to rupture, twenty-one, or 60 per cent, came into the hospital within twenty-four hours after onset of symptoms, and only four later than four days. The younger the child the less likely will its abdominal pain receive early serious consideration. In the nonperforated acute group, the average age was nine years and the youngest child five, while in the perforated cases the average was six with twenty-five children *less* than five years of age. The not infrequent association of sore throat, nasal colds, and middle-ear infection with the onset may further lead to a mistaken diagnosis and delay, and physics continue to be given in most cases. In this series nine children had a severe cold or sore throat at the onset, one had an otitis media, one had pneumonia, and another had an empyema; and at least twenty-nine had been given physics. The presenting complaints were quite varied. Some 76 per cent complained simply of pain in the abdomen, while in the remaining number the complaints were scattered among the following: fever, sore throat, sick, pain in the navel, and vomiting; and in only 12 per cent was the presenting complaint "pain in the right side."

---

* Read before the General Surgery Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

PHYSICAL FINDINGS

As to the physical findings: localized tenderness and rigidity occurred in 80 per cent, with some generalized tenderness in 50 per cent, generalized abdominal distention in 25 per cent, and a palpable mass in about 25 per cent. Acutely inflamed throats were present in six (10 per cent), two had signs of pneumonia, and one an empyema. The average white count was 20,432, as compared with an average count of 16,692 in the acute appendix. The urines of only nine were negative throughout; twenty-two had an occasional pus cell; three had numerous pus cells; eight had an occasional red and pus cell; albumin was present in four, and acetone almost without exception. These findings, as given, obviously have nothing to do with the management of the ruptured case. I am merely pointing them out to show the various pitfalls that allow such a high proportion of children to go on to rupture.

OPERATIVE PROCEDURES

Notwithstanding that there had been serious delay in bringing the children to the hospital, the interval from admission to operation was only an average of six hours. Although I believe it is quite universally agreed that operation should be delayed until localization has taken place in an obviously spreading generalized peritonitis, yet one should weigh heavily the possibility of a localized lesion becoming generalized while procrastinating.

The type of incision in this group was about equally divided between the classical McBurney incision and some type of right rectus incision. Though the duration of stay in the hospital was somewhat less in the former, it is quite evident that in the right rectus group we were dealing with children seriously ill, and with a greater percentage having a generalized infection. McBurney's incision is, however, to be preferred in cases of well-defined localized abscess where one can cut directly down on the abscess without opening the general abdominal cavity.

The appendix should be removed in all instances where one can do so, without mauling and without getting into clean territory. In this series the appendix was removed in forty-six of the fifty-five cases. Drainage was established in all fifty-five patients, including the eight with generalized peritonitis. While I am not convinced of the value of drainage in generalized peritonitis, it is obvious that drainage continues to be considered the method of choice at the Children's Hospital. The ruptured appendices can be roughly placed into three groups: (1) The group in which there is a well walled-off abscess, where only local drainage is necessary. (2) The group in which there is only moderate walling off, with localized peritonitis. In this group I prefer to place one Penrose drain in the right gutter, one in the ileocecal region, and one to the pelvis. (3) The generalized peritonitis group. In these one should either not drain at all, or copiously.

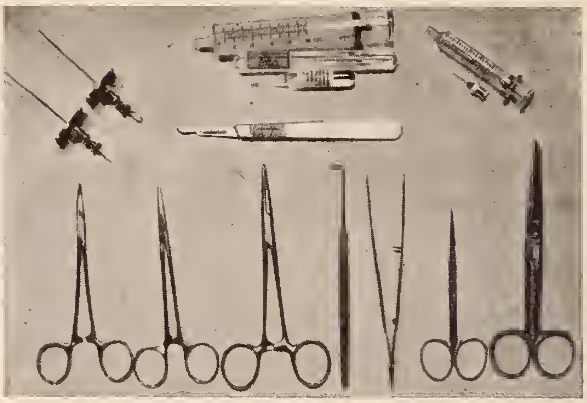

Fig. 1.—Tray setup showing armamentarium used for venotomy.

Frankly, I do not believe that we have made any advancement whatsoever in operative technique in the past fifteen years. There has been, however, one distinct singular advancement in the postoperative care of these children. I refer to the use of the continuous glucose drip, or venoclysis, in association with the indwelling nasal tube.

CONTINUOUS GLUCOSE DRIPS VENOCLYSIS

Without exception every child with a ruptured appendix has acetone in the urine. Formerly the administrations of fluids and the combating of ketosis, toxemia, and hypochloridation had been a notoriously haphazard routine in children. Proctoclysis was not tolerated at all in children, hypodermoclysis poorly, and repeated intravenous injections were most difficult to administer. Since the introduction of the slow glucose drip by Matas, this method of administering fluid has been in constant use in the various departments of the hospital with, I believe, universally gratifying results.

Armamentarium. — The armamentarium used is relatively simple, as shown in the illustration (Fig. 1). A separate tray is set up, having chiefly small scissors, mosquito forceps, a small Bard-Parker knife, a small aneurysm needle, 00 catgut and several intravenous needles of different sizes. The solutions and apparatus which we have been using is that prepared by Baxters, which consists of an inverted bottle with air-vent tube, tubing and clamp, and a drip bulb somewhat like the Murphy drip, but without the hole in it.

Technique of Venoclysis. — Having decided to use the drip method, it is best to start it while the child is still under the anesthetic on the operating table. In order to save time an assistant may work simultaneously on this while the operation is in progress.

In children it is decidedly simpler to use a vein in the leg than one in the arm, as it is easier on

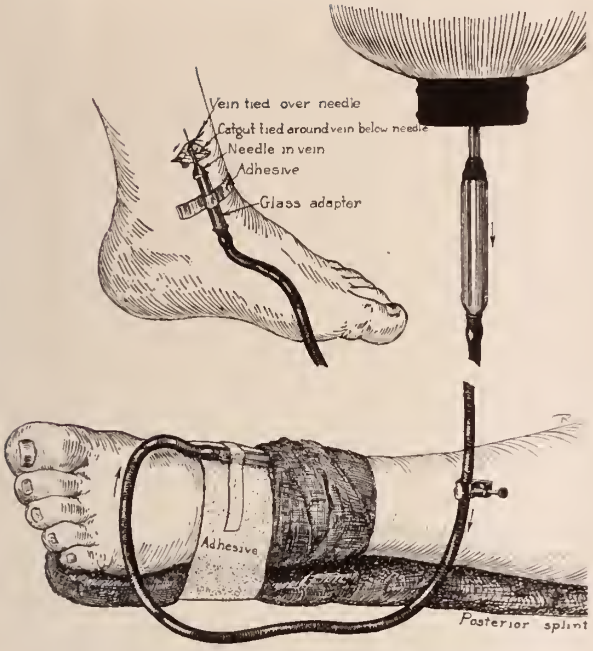

Fig. 2.—Upper sketch shows needle introduced into vein by cutting down just above internal malleolus. Lower sketch shows needle in place connected to venoclysis set and posterior splint applied.

the child, handling is facilitated, and there is not the likelihood of the child pulling it out. It has also been the experience of the residents in the hospital that phlebotomy is preferable to simple introduction of a needle into the vein, not only because of difficulty encountered in introducing a needle into the small vein of a child, but also because it has been felt that thrombosis and occlusion of the needle does not occur as soon where the needle is introduced through an incision and the vein tied, over and behind the needle.

The left leg, being the most accessible, is used (Fig. 2). A padded posterior splint is applied posterolaterally from heel to thigh. A tourniquet may be used, but is not absolutely necessary, as the great saphenous vein may invariably be found by cutting down just above the anterior portion of the internal malleolus. An incision, therefore, transverse to the leg is made about one finger's breadth above the anterior portion of the internal malleolus. The vein is identified and freed, and two 00 catgut sutures carried beneath, tying the most distal one above the vein and leaving the upper one to be tied over the needle after it has been inserted. A small V-shaped opening is then made with a small scissors, the needle is inserted, the glucose apparatus solution connected, and the upper catgut tied above the vein. A stitch or two may be taken in the skin, and the tubing secured to the leg with adhesive. The first 100 cubic centimeters of solution may be allowed to run in rapidly, and then the frequency of the drop cut down to the desired number per minute. The accompanying table was compiled by Dr. R. W. Mapes of the hospital, and shows a rough schedule for the amount of fluid given these children of various ages, and the estimated number of drops per minute necessary to maintain that intake (Table 1.)

Table 1.—*Outlining Amount of Fluid Given to Children*

Age	Solution	Amount in 24 Hours	Number of Drops Per Minute
Infants up to 2 years	5% glucose in normal saline	60 cc. per pound body weight	6 drops a minute per pound body weight
2-8 years	5% glucose in normal saline	1,200-1,500 cc.	75-95 drops per minute
8-12 years	5% glucose in normal saline	2,500 cc.	130-140 drops per minute

On completion of the anesthetic, with the patient still on the operating table, a nasal tube is passed into the stomach and secured to the side of the face with a strap of adhesive. After the child has been returned to its bed (Fig. 3), the leg is elevated and the drip per minute regulated. The nasal tube, carried to one side of the bed, is left open for constant drainage, and the nurse is instructed to lavage every two hours with two ounces of five per cent soda solution. Wristlets are then applied as illustrated, allowing plenty of freedom, but preventing the child from pulling out the nasal tube or getting at the dressings. We have allowed these children to take sips of water as they wish, since none of it is retained; it gratifies their thirst, and acts as a gastric lavage. By this simple method of treatment the patient is quite comfortable, ketosis disappears within twenty-four hours, a proper chlorid fluid and glucose intake is established, distention is reduced, and the necessity of enterostomy becomes practically nil. Both the nasal tube and glucose apparatus are, as a rule, retained for about four days without trouble. With the apparatus used, glucose reactions are indeed rare. I am informed by Doctor Hyland that he has encountered one fatal anaphylactic reaction, and one in which emboli were present in the leg which could possibly have been attributed to the venoclysis: this out of several thousands that have been given in the hospital in the past five years.

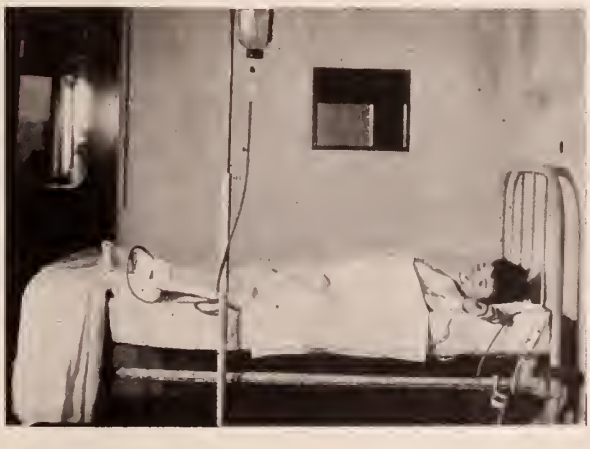

Fig. 3.—Photograph showing glucose drip setup and nasal tube inserted.

We have felt that pitressin has helped in the prevention of postoperative distention and paralytic ileus. Potter and Mueller of Bellevue Hospital have shown that the effect of the drug was merely that of maintaining tone, and that there was no clinical evidence of increased peristalsis. The amount given varies according to the age of the child. A fourth to a half cubic centimeter is given every four hours for three days, the first dose being administered directly following the operation, when copious hot packs to the abdomen are, likewise, begun. For postoperative sedatives the insertion of a rectal suppository, containing three-fourths grain of sodium amytal for infants below two years and one and one-half grain for older children, gives gratifying relief. This is fortified by codein or morphin, bearing in mind the danger of giving morphin to the infant.

POSTOPERATIVE COMPLICATIONS

Postoperative complications are varied and must, of course, be managed as they appear. In the series a fecal fistula developed in one which closed of its own accord. In another, after the drains had been removed on the seventh day, an abscess formed, which four days later spontaneously ruptured into the bowel. Another case developed an acute intestinal obstruction on the fourth day. Two children developed postoperative pneumonia. One developed an acute mastoid, and another developed an acute middle ear. A subdiaphragmatic abscess with a secondary empyema occurred in one. Bilateral parotitis, with recovery, occurred in one. Of the eight cases of generalized peritonitis, three recovered and five died.

CONCLUSIONS

The high incidence of 55 per cent of perforated appendices in children is due almost entirely to delay. If we are going to get anywhere at all in reducing this appalling percentage, it is up to the medical profession to repeatedly remind the public of the possible danger of appendicitis in any ordinary so-called "stomach ache" in children, and to persistently warn against the promiscuous use of laxatives before appendicitis has been definitely ruled out. So far, certain insurance companies and drug firms have carried on a distinct educational campaign in this regard, but the medical profession has not undertaken any definite educational program in this respect.

The frequent associations of nasal colds, sore throats, and middle-ear infections are particularly misleading, and parents as well as physicians must realize that their presence with an abdominal pain does not necessarily rule out appendicitis.

The use of the continuous glucose drip in conjunction with the indwelling nasal catheter has been a distinct advance in the postoperative care of these children, not only in that it provides greater comfort, but also in that normal body chemistry is restored and toxins relieved in the quickest possible manner.

939 Pacific Mutual Building.

DISCUSSION

William J. Norris, M. D. (1136 West Sixth Street, Los Angeles).—The number of cases of ruptured appendices mentioned by Doctor Baumgartner is sufficient reason for bringing up this subject even more frequently than has been the case in the past.

There are certain facts that should be borne in mind when examining children in an effort to determine the presence or absence of an inflamed appendix. The approach to the patient should be studied, and sufficient time taken to gain the child's confidence in order that real muscle spasm may be differentiated from the spasm present in an apprehensive child.

The existence of diarrhea, associated with a ruptured appendix, is far more common than seems to be generally recognized, so that one should not be misled, as Doctor Baumgartner has indicated, by the presence of symptoms not commonly associated with this condition. A rectal examination will frequently make a diagnosis, and is altogether too commonly overlooked.

The question of when to operate is always one which gives rise to differences of opinion. The only cases, in my humble opinion, which should be observed, are those in which a definite history of improvement before the time of consultation has been obtained. If a child, said to have been an extremist two or three days previous to the time of its being seen by the surgeon, has definitely improved in every way, and there is evidence of localization, it would seem advisable to wait for further localization. With this one exception, I believe that operation is indicated following the restoration of body fluids.

The continuous drip, associated with an indwelling stomach tube passed through the nose, has without question saved many lives, and, as the essayist has stated, should be routine treatment where indicated.

In a series of one hundred cases which immediately preceded this past one hundred cases, the percentage of ruptured appendices was sixty-five in contrast to the 55 per cent just reported. This should encourage us to continue our efforts to educate parents and assist doctors in making early diagnoses.

⁂

Ezra S. Fish, M. D. (9615 Brighton Way, Beverly Hills).—Doctor Baumgartner's paper brings out forcibly the high incidence of perforated appendices that occur in children. While it is true that perforation of the appendix is prone to occur more quickly in childhood, the chief reason for the high incidence, as Doctor Baumgartner has emphasized, is delay.

One would not think it necessary that so much emphasis should have to be placed upon the fact that appendicitis does occur in childhood, and upon the necessity of early diagnosis.

Apparently, the idea of dietary indiscretions—food upsets and stomach upsets, causing fever and abdominal pain—is so firmly imbedded in many parents' minds that the possibility that their child has an inflamed appendix does not occur to them. Many parents, further, are under the impression that children do not develop appendicitis.

To remove such misconception and misunderstanding, it is obviously necessary that the danger of appendicitis be continuously brought to their attention by such a paper as Doctor Baumgartner has presented here. I agree entirely with him in his plea that the medical profession add their efforts to those of the insurance companies and other agencies in developing an educational program that will make the public, first, appendix-conscious and, second, fearful of the danger of delay.

⁂

George Thomason, M. D. (1219 Hollingsworth Building, Los Angeles).—Any discussion is profitable that will make clearer a disease ordinarily dangerous at any age, but doubly so in the very young. Doctor Baumgartner has thrown considerable additional light on the subject in his illuminating paper.

In young children acute appendicitis is certainly more treacherous than it is in later life, because of:

1. Greater difficulty in accurate early diagnosis.
2. The greater frequency with which cathartics are given; in which case, as Lord Moynihan states, "the mere giving of a laxative is indication enough for instant operation," but which procedure, unfortunately, is not sufficiently frequently adopted because of the persistent belief on the part of parents that the case is one of indigestion,

and more purgation is likely to be resorted to rather than the calling of a physician.

3. The relative shortness of the omentum in children, preventing the proper functioning of this tissue in walling off the appendix area as it so helpfully does in adult life. Thus general peritonitis is made more possible in children than in cases of appendicitis later in life.

4. The thinness of the appendiceal wall in children undoubtedly leads to more frequent rupture of the appendix in children.

5. The comparative inadequacy of its blood supply, which is a terminal blood supply in the appendix, making more possible rapid degenerative processes, particularly in the meso-appendix, extends only half the length or less toward the tip of the appendix. This is illustrated in Doctor Baumgartner's paper, in that he states 55 per cent of the cases had ruptured.

6. In children the usual regular sequence of symptoms and findings is by no means so constant, therefore resulting too frequently in a wrong or a delayed diagnosis of the true condition.

In dealing with children suspected of having acute appendicitis, one should surely constantly keep in mind the possibility of pneumonia. There are, undoubtedly, cases in which children are operated for supposed acute appendicitis, and in which pneumonia is an apparent postoperative complication, when, in fact, it is primarily a case of pneumonia in which an appendectomy has been performed.

Adams and Berger reported a typical series of 145 cases of pneumonia in patients between two and fifteen years of age, in 17.5 per cent of which the diagnosis was acute appendicitis.

In every case the chest should be very carefully examined. In pneumonia in a child, there is usually a higher temperature and higher leukocyte count, a different type of breathing, and the noticeable characteristic movement of the alae nasi, but often the temperature and leukocyte count may at times fail to lead one to a correct differentiation.

The outline Doctor Baumgartner gives so specifically with reference to the postoperative care is to be most highly commended. We believe it a good plan to siphon the indwelling nasal tube at different intervals and then to close it for a time, unless nausea be present, in order that the upper intestinal secretions be not entirely lost through constant drainage.

LATENT SYPHILIS*

By William H. Goeckerman, M. D.
Los Angeles

Discussion *by George V. Kulchar, M. D., San Francisco; Harry E. Alderson, M. D., San Francisco; Louis F. X. Wilhelm, M. D., Los Angeles.*

WEBSTER defines the meaning of the term latent as not visible or apparent, concealed, dormant. Strictly speaking these meanings can be applied to a syphilitic infection, with reservations only. It should be recalled that the process may be pathologically or biologically active, yet not apparent by any clinical examination at present at our disposal. I will, therefore, use the term as meaning nothing more than clinically not recognizable syphilitic infection at the time of examination. A clinical diagnosis of latent syphilis assumes a very careful physical examination by all the means at the command of modern medicine. If such an examination is negative, the diagnosis must rest on a positive serologic test, on a clear-cut history of infection, in the female on the birth of a syphilitic child, under special circumstances on gland puncture or biopsy, and finally a necropsy. The common knowledge, that we may be dealing with a clinically unrecognizable infection in the presence of a pathologically and biologically active process, presents a fascinating but at times difficult treatment problem, both from the standpoint of the individual and the public health.

COMMENT

There seems to be no division of opinion on the necessity of systematic treatment to prevent spread of a syphilitic infection, including transference of the disease to the progeny. When the probability of contagiousness is still present and the patient is not intolerant to the drugs now usually employed, treatment is obviously indicated. When it is a question, however, of the individual's future welfare and the prevention of late complications, the treatment problem becomes decidedly more complex and should not be met in a routine manner. Various modifying factors must be considered before deciding on the course to be pursued. Most observers no longer accept Ehrlich's idea of "therapia sterilisans magna," in the treatment of syphilis, except possibly in the very earliest stages of the infection. In the latent stage the infected individual's immunity mechanism becomes the deciding factor. The chief function of antisyphilitic treatment at this stage is to increase the efficiency of this mechanism. How effectively this can be done is still debatable. There are some who believe that modern treatment predisposes to, rather than prevents late internal complications. Attention has also frequently been called to the possibility of the arsphenamins and heavy metals producing injury to vital organs, which only becomes evident many years later. Probably the only way the exact value of modern treatment can be appraised is a comparison of a large series of patients observed over a whole lifetime, treated as well as untreated. Obviously this is practically an impossibility at the present time. Bruusgaard[1] was able to study a fairly large group, which had never received any treatment, years later. This group was seen in the early and secondary stages, and therefore, not strictly confined to a group that has achieved latency. None the less his findings are significant. According to his studies, untreated syphilis usually runs a benign course, and may frequently be completely eliminated by the patient's own powers of immunity. He makes no claims, however, that might contraindicate modern treatment. His data, also in my opinion, do not speak against judicious treatment. Since treatment must be carried on, let us consider the factors which determine the type, and amount of it in a given case during the latent period.

AGE AND LATENT SYPHILIS

Obviously a youthful individual, sexually active, with the infection of a few years' standing, and viscera in good condition, presents a different problem from the individual who shows no detectable clinical evidence after having carried the infection for many years, whose sex-life has be-

207278

come of minor importance, and whose vascular mechanism no longer has the proper resiliency. In the former, intensive treatment is by far more desirable than in the latter. In the latter, it is usually much better to follow the principle of stimulating his immunity mechanism than to try to achieve sterilization by strictly massive dosage.

WASSERMANN-FAST LATENT SYPHILIS

The significance of Wassermann fastness in latent syphilis is still not settled. Some observers believe that this phenomenon may simply be a part of the immunity reactions in some patients who harbor the Spirochaete pallida. Studies such as those of Stokes and Busman [2] suggest that a positive serology signifies an active infection. According to their findings it is likely that a diagnosis of latent syphilis is dependent upon the defects of our diagnostic procedures. Warthin's[3] observations also point in this direction. Every syphilographer knows, however, that many a patient with persistently positive serologic tests continues through a whole lifetime without ever showing clinical complications. My own belief is that, while there is a degree of activity in such patients, the immunologic mechanism is so effective that the damage is not sufficient to produce clinical symptoms. It is particularly in such patients that observation for the rest of their lives is desirable. There is every evidence that the serologic tests will eventually become negative in most of them, but there is no necessity to try to achieve this at all hazards by intensive treatment. In fact, in about 30 per cent, this cannot be done. I do not believe that we are dealing with a true latency, such as is seen in the diphtheria carrier for instance, in such cases. A good rule here is to treat the patient, not the serologic tests. If the individual's physical condition is good, every effort should be made to give adequate modern treatment. Methods, of course, vary in the best hands and may be found described in good textbooks. Very enlightening in this respect are the Coöperative Clinical Studies in the Treatment of Syphilis.[4] It would seem good judgment to emphasize the use of the spirocheticidal drugs in the early years and the resistance builders, if such we have, in the later years of the latent period.

THE SPINAL FLUID IN LATENT SYPHILIS

It is a well-known fact that the spinal fluid is positive in a large percentage of syphilis during the early period. As latency becomes established, the fluid has a tendency to become normal either with or without treatment. When the fluid has a tendency to remain positive, it constitutes a definite menace to the future health of the patient, and without treatment practically means eventually some complication referable to the neuraxis. If such a patient has had a reasonable amount of routine therapy and the fluid remains positive, other measures must be considered. Conversely, if the spinal fluid is negative when latency has been reached, the danger of complications and the necessity for repeated spinal fluid examinations become negligible.

PREGNANCY AND LATENT SYPHILIS

It is pretty well conceded that pregnancy has a beneficial influence on the course of syphilis, and the prognosis as to freedom from clinical complications is definitely better in a woman who has borne children. This does not mean, however, that she is not potentially dangerous to her progeny even in the later years of latency. The necessity for careful consideration of treatment is, therefore, much greater in such a patient if there is a probability of future pregnancy.

MARRIAGE AND LATENT SYPHILIS

The question of marriage is usually raised during this stage, and often a difficult one to decide. No definite rules can be stated and each case must be considered on its merits. It can be said, however, that the danger of infecting the partner is much less in the late than in the early latent period. The contagious factor becomes minimal with consistent treatment, and no tendency to relapse. The tendency to late complications and invalidism is not negligible, however, and should always be considered in permitting marriage. Another consideration is the transmission of the disease to the progeny. While an important one, it is not vital because of the effectiveness of preventive treatment of the mother. It is my practice also to consider the age of the contracting parties, and their economic status.

CARDIOVASCULAR SYPHILIS AND LATENCY

All modern studies indicate that involvement of the cardiovascular system may not be recognizable clinically for many years. Sometimes the manifestations are so insignificant that they remain obscure throughout a lifetime, but are quite apparent at necropsy. Much evidence is accumulating that the vascular involvement is a very early one. It is apparent that, if treatment and the patient's immunity mechanism do not eliminate the infection, it will be permanent. Yet the percentage of cardiac invalidism resulting from syphilis is a comparatively small one. There are, however, many students of the disease, particularly in the French school, who believe that syphilis is a very big factor in many forms of cardiac disease. If Warthin's[5] observations are correct, and I believe they are although I cannot agree with his deductions, the heart is particularly apt to harbor the spirochete for a whole lifetime.

My inclination is to be optimistic in regard to the future of the patient who has contracted syphilis, especially if he reaches the latent stage without any pronounced tendency to clinical relapse. Even in patients not treated or very poorly treated, the disease in the majority of instances runs a benign course. With proper modern care it is possible to reduce contagiousness to a minimum, and if the patient will treat before complications have set in, the prognosis for the future in the main is good. I am inclined to this opinion despite of the rather discouraging findings reported by Warthin[6] and other pathologists. I think it can frankly be said that even at present only a small percentage of patients with syphilis receives adequate modern treatment, either during the early stage or when latency has been reached.

1680 North Vine Street.

DISCUSSION

George V. Kulchar, M. D. (450 Sutter Street, San Francisco).—At the present time our concept of latency is that of a period of high resistance and low visibility, with an undercurrent of mild inflammatory changes taking place in vital structures. Although virulent treponemata are present in the body, the balance between the host and the invading organism is temporarily or permanently maintained.

The clinical diagnosis of latency is tenable only when the careful examination, laying particular emphasis on the cardiovascular and central nervous system, has revealed no lesions definitely attributable to syphilis. The cerebrospinal fluid must be negative. The more closely we examine our patients, the fewer will be the number that fall into this group.

The blood Wassermann reaction, save as an aid to diagnosis, is of minor importance during latency. The Wassermann that remains persistently positive demands a careful examination to rule out visceral and neurosyphilis. Once this has been definitely eliminated, the Wassermann can be more or less disregarded. While the percentage of Wassermann-fastness varies with the sensitivity of the technique used, the studies of the coöperative clinical group have indicated that Wassermann-fastness in latency in no way alters the prognosis for cure or relapse.

Regarding the cerebrospinal fluid, it is apparent, from recent studies, that if this is negative during latency, the patient may be virtually assured, aside from vascular involvement, that the central nervous system is to be spared.

The decision when to treat the latent syphilitic is sometimes a difficult one to make. Despite the relatively benign course of syphilis, as indicated by Bruusgaard's studies, the relative crudity of our methods of examination, and the very small and isolated lesions in vital structures capable of producing the most disastrous consequences, make it desirable to lean toward the side of treatment. However, if the patient is beyond the age of fifty, and it can be established that the infection is of more than twenty years' standing, treatment is not necessary. In order to safeguard the immunity relations in latency, treatment should not be started unless it will be carried to completion. The standard course of treatment should include twenty injections of an arsphenamin and from forty to sixty injections of heavy metal, preferably bismuth. In early latency, treatment should be continuous; but if the infection is more than four years' duration, rest periods apparently do not influence the ultimate outcome.

While the natural tendency of syphilis is toward spontaneous cure, by treatment of latent syphilitics, the percentage of satisfactory results, as measured by prolonged good health and freedom from manifestations of syphilis, can be increased from 35 to 85 per cent, and progression and relapse decreased from 20 to 30 per cent in untreated latency to from 2 to 5 per cent by adequate treatment.

⁂

Harry E. Alderson, M. D. (490 Post Street, San Francisco).—The author has presented this difficult and more or less obscure question in a very interesting manner. He leaves little additional to say. In my opinion, for the present, we shall have to regard all patients with persistent complement-fixation reactions and no other symptoms as having foci of treponemata pallidae in some organ or tissue.

The treatment, however, should depend largely upon the age of the patient. Naturally, young persons with latent syphilis may have children, and they should have persistent treatment until the serologic signs are favorable, provided *there are no contraindications*. Arsphenamin, bismuth, mercury and the iodids should be given along with some form of shock therapy, and every effort should be made to build up the patient's resistance by means of various forms of physiotherapy.

With elderly patients whose infection apparently has not done any serious damage and who are clinically well, to my mind it is better not to run the risk of injuring important organs by heavy antiluetic treatment. Such patients should be given mercury, or bismuth and iodids, more or less continuously. They should be checked up occasionally and naturally in the presence of complications, more active therapy given then, cautiously. We all have seen elderly syphilitic patients who were doing very well until active antiluetic therapy was started, and then developed serious troubles attributable to the treatment.

Until we know that a persistent Wassermann may exist in a nonsyphilitic patient, we shall have to continue to treat these individuals. This question may be settled within the next few years.

⁂

Louis F. X. Wilhelm, M. D. (727 West Seventh Street, Los Angeles).—The management of latent syphilis, as brought out by the author, often is a real problem. The age of the individual, naturally, is a real factor in determining one's approach. In recent years, with the more general use of the serologic tests, many cases of otherwise unrecognized infections are uncovered. If we find a latent syphilis in an individual past the three-score age, we need not be concerned with treatment. On the other hand, when we are dealing with an individual in the twenties, or even thirties, our whole approach changes. Here we must treat the infection. The paper of Stokes and DesBrisay, in which they present the results of several hundred cases of late complications, would compel one to insist on adequate treatment. They found that the extent of severe late complications was almost directly proportional to the degree of inadequacy of the previous treatment in the early years of the infection. In other words, the severity of late complications became definitely less as more and better treatment had been givn. The greatest number and severest complications were found in those individuals who had received absolutely no treatment. Oral treatment with the iodids showed a definite though slight benefit. The addition of mercury by the mouth added another slight improvement. The use of intramuscular injections of mercury again showed better results. Finally, the addition of the arsphenamins showed the group with the least complications. This study certainly agrees with the author's view that latent syphilis should receive carefully controlled, adequate treatment.

⁂

Doctor Goeckerman (Closing).—I am glad to note that the discussion agrees on judicious individualized treatment of latent syphilis. It is apparent that a persistently positive Wassermann is an incidental finding, and does not necessarily require intensive treatment to reverse it. On the contrary, the patient, not the Wassermann test, needs the treatment.

THE LURE OF MEDICAL HISTORY[†]

RATIONAL OR LIBERAL MEDICINE[*][‡]

AS UNDERSTOOD SOME "FIFTY YEARS AGO"

By Joseph P. Widney, M.D.
Los Angeles

PART II[**]

MEN sometimes ask me of what school of medicine I am. I am always puzzled to answer.

Schools in science imply distinctive theories or dogmas. As there are no such distinctive theories or dogmas to this, it can have no specific or definitive name. It is simply the science of medicine, as one speaks of the science of chemistry, or of astronomy. I can only reply: "I am a physician; and my system is only known as the science of medicine; because of its freedom from hampering dogmas, and instead its search after causes, it might be termined "rational medicine"—sometimes called regular medicine. It is sometimes, by persons unacquainted with it, called allopathy, but mistakenly. It might as well be called hydropathy, or homeopathy, or eclecticism; and yet it is neither. And yet, in a certain sense, it is all of these; for all of them are only one-sided views of some phase of its broader and more rational development. As before stated, distinctive names imply dogmas, and dogmas are narrow and one-sided. They belong to the early, the youthful, the immature ages of science. Schools of medicine, or of any science, belong to a lower plane. On the higher plane of true science, schools drop away. Science is one. There was a time when one might ask of an astronomer, or of the chemist, to what school of astronomy or chemistry do you belong? Now we do not ask so. With increasing knowledge the schools have dropped aside. Now the reply would be simply: "I am an astronomer," or, "I am a chemist."

So in medicine. Rational medicine has passed beyond the narrowness of restrictive dogmas, and calls itself by no distinctive name. It is only the science of medicine; and its practitioners call themselves simply physicians.

ORGANIZATION OF THE PROFESSION OF MEDICINE

The profession of medicine is organized, as are the other professions, because through organization the ends of science may best be furthered. Organization does not imply sameness of thought or views. Probably no two members of the profession think in all things alike. This is not the object or purpose of organization. An organization which meant dogmas and sameness would be death to progress. These are the things which it seeks to avoid. Its constant labor is to encourage variety and originality of thought. The objects of organization are:

To combine forces for more successful and thorough investigation of questions of medical science, and to diffuse information about new discoveries and advances. As illustrations may be cited new discoveries and advances. As other expressions may be cited the monthly meetings of the numerous county medical societies all over the land, the annual meetings of the state and national medical associations, and of similar bodies in all civilized lands, and the periodical gathering of the International Medical Association. Also may be cited the hundreds of medical and surgical journals published all over the civilized world.

A second object of organization is to carry on more successfully and thoroughly the work of medical education. As results of this may be pointed out the colleges of medicine which dot all lands, with their large aggregation of capital invested in buildings, libraries, scientific appliances, and the extensive laboratories for experimentation connected therewith. This heading may also include the duty of establishing and enforcing among the colleges a recognized standard of efficiency and thoroughness in educational work. The fruits of this are seen in the progressive advancement from the simple pupilage, for a short term, under some practicing physician, or the single course of lectures of the earlier ages, to the two years, and now the three years, of carefully graded lectures and hospital work, and the rigid examinations, before the student becomes eligible to the degree of Doctor of Medicine. And recognition is refused to colleges failing to adopt, and in good faith observe, such advanced requirements in their educational work.

Again may be mentioned, as among the objects of organization, the discouragement of narrow and obstructive systems or schools of medicine.

And, finally, may be mentioned, to establish and maintain a code of ethics for the profession. Recognizing, even in the earliest ages, the semi-sacred character of its calling, the profession has ever laid down, for the guidance of its members, rules of conduct, defining their duties to the sick, to community, and to each other.

The Hippocratic oath, which is probably the oldest code that has been saved to us, and which twenty-three centuries ago was administered to the physician upon commencing his practice, had in it the groundwork of a strong ethical morality; and from that day to this, through all the long ages, the moralities of the profession have never been lost sight of, and the oath of Hippocrates has broadened out into the pure and lofty code which is made binding upon every physician, and which in the fullness of its requirements does not yield precedence even to that imposed upon the minister or the priest when admitted to his sacred calling. It is true, many unworthy members of the profession fall far short of its standard in their daily conduct; yet the code is there, ever standing as a written reproach to them, and in proportion as they fail to come up to its requirements they lose caste and standing among the more honorable members of the profession.

RELATION OF RATIONAL OR LIBERAL MEDICINE TO THE VARIOUS SCHOOLS OF MEDICINE

By bearing in mind what rational or liberal medicine is aiming at in its own development, it is easy to infer what must be its relationship toward the various schools, or systems of medicine, which from time to time spring up. It is itself aiming at freedom from dogmas, for these inevitably lead, as it has too often discovered in its own history, to narrow and one-sided generalization.

It has in all these ages of seeking after truth so often felt the evil of such things that it has learned to beware of them. It therefore says to schools or systems basing themselves upon fixed dogmas:

These things belong to the past: modern science has grown beyond them. Such dogmas imply narrowness. It is a step back toward the dark ages again. Only the broadest freedom of investigation should be recognized in scientific research. Because you have thus abandoned the broader field, and have restricted your research to the narrow limits of a fixed and unchangeable creed, we cannot accord to you full recognition as broad and progressive members of a liberal profession. Science knows no boundary lines of creeds; and in the ranks of scientists the days for shibboleths have gone by. It is *because* you have abandoned the broader field of rational medicine, and *because* you are hydropathic physicians, or eclectic physicians, or homeopathic physicians—men whose science is bound up by a preconceived and inflexible theory, and because you are not simply *physicians,* men free to seek for, and to use, truth wherever found, that you are not accorded recognition as worthy representatives of a liberal and rational medicine. It is because you load yourselves down with clogs in the shape of *pathies,* and tie the load on by a distinctive name. Liberal medicine refuses to so encumber itself with clogs: ties itself to no set theories: binds itself by no name distinctive of a fixed creed: and so has to unload itself of no fixed burden of clogs when it would advance.

To the individual members of these schools Liberal Medicine says: Recognition is not withheld from you because you, as individuals, hold some theories of disease and of treatment which we consider narrow and ill-founded, for many individual men within the ranks of liberal medicine hold opinions probably deemed by their fellows equally odd, and yet are simply looked upon with a lenient smile as men who have some queer fancies; but it is because you elevate the fancy into a dogma, and build thereon a sect, and tie yourselves to it, making it a restrictive creed for education, and a test of standing. It is not because you, as an individual, are considered to hold only a partial truth, for many within the ranks of regular medicine fail to grasp the breadth of its teachings, and all their days are only as lame men in the pathway, but because you insist that this is all of truth and restrict yourselves to it.

Liberal medicine has tenets and treatments which resemble from one point of view homeopathy, others which resemble hydropathy; but it recognizes the fact that these are only partial and incomplete views, and are not all, but that more lies beyond. It lifts its eyes from the single hills toward the eternal highlands which it knows must tower through the mists above and afar. It may as yet catch only partial glimpses of that higher ground of medical science, but it feels that somewhere, on through the mists, it lies; and will be content with no resting place that is short of that goal. And it may be that the limits placed upon human knowledge by human weakness make the goal an unattainable one. Still it will climb the higher by being content with nothing less.

Another reason why the profession of liberal medicine has declined to accord recognition to these various schools and systems, is the character of the educational work which they permit within their ranks.

The constant struggle of rational medicine is to raise the standard of education. Under this endeavor the standard has been raised, as has already been stated, from the old-time country reading and a certificate, or possibly a single course of lectures, to a three years' graded course, with clinical work in the hospitals, and rigid examinations. And the tendency is toward a still higher standard. It is not unfair to say that this effort to raise the standard of education upon the part of liberal medicine has not been met by a corresponding effort among the schools or systems enumerated. While there have been some honorable exceptions, the general standard has been low, and without a well-expressed desire or intention of a change. It is no unfair or unjust rule which rational medicine applies to these schools, for it applies the same test to itself. The so-called college of rational medicine which does not conform to the requirements of the higher education, or which lowers its grade, at once loses caste, and is refused recognition. And this is the point in which those of the schools in these systems, which attempt the higher education, fail of reaping the just fruits of their more honorable work. For instead of declining to recognize the colleges which cling to the inferior standard of education, they continue to recognize them as legitimate institutions of learning, and admit their defectively educated graduates to an equal standing with their own who have honestly done better work. In this way they practically neutralize the effect of their efforts to elevate the standard of their colleges.

A very proper reply was given a few years ago by the English National Association of Physicians to an application upon the part of a numerous body of one of these schools for recognition by the regular profession. The reply was this:

"Before we were recognized as fitted to become members of the profession we had to go through a thorough course of study, and pass rigid examinations. Give proof that you can stand the same tests and you will receive recognition."

The offer was declined, and of course recognition was withheld.

This rigid stand is taken by the profession of liberal medicine upon the question of education, because it is felt that where human health and human life are at stake only the most thorough possible preparation for the work should be tolerated; for even then the physician will too often be made to feel how limited are his powers of relief, and how much yet remains to be learned.

THE FUTURE OF MEDICINE

Medicine is not yet an exact science. Possibly it may never be, for of all branches of human knowledge it probably is hedged about by the greatest difficulties. Yet it stands today far in advance of its position a century ago; and a century ago it stood in advance of its position of a century before. Age by age it is climbing higher. Age by age it is penetrating deeper and deeper into the mysteries of disease, of its causation, of its cure. And no one realizes with more sadness than does the educated physician the vastness of the field which is still a terra incognita; and no one who has not stood with him in the midst of the perplexities and anxieties of his toiling, can realize the keenness with which he feels the slurs so often wantonly cast upon his work by tongue and by press. It is a cruel wound to give to what is probably today the most conscientiously self-sacrificing of all the callings of man. The cruelty of the wounding can only be excused by its thoughtlessness. I, who, after years of toil in this work, am no longer seeking its rewards, may say these things as one might not who may be but just entering upon its labors. I plead for the incoming generation of toilers in this sacred field, a juster appreciation upon the part of that public to whom the toil is given. And I plead a juster discrimination in judging of men. To the public any man who puts up his sign and calls himself "Doctor," is a physician. And yet many of these are men without even the pretense of medical education. And for their misdeeds, for their ignorance, the profession must share the obloquy and the shame, for the public does not stop to discriminate. And yet it is not the fault of the legitimate profession of medicine that such is the case. Scarcely a session of a legislature goes by in any state that the request does not come up from the organized profession for laws to weed out the unworthy; for laws establishing tests of examination as to knowledge and scientific attainments, before men shall be permitted to take into their hands the care of human life.

"We," they say, "who daily are called upon to witness the harm done by men who have in no way qualified themselves to battle with disease, and yet who, with mercenary motives, enter upon the work, we ask you to establish tests; require examinations; make men first prove their fitness, as you do with engineers upon your steamboats, or with lawyers at your bar. We ask no favor. We do not ask exemption from the working of the law for ourselves or for our colleges. Require the test of all; and then debar the ignorant, the unworthy, from entering upon this work."

This is what the profession asks. It is the public which through its representatives refuses; and, where laws are passed, through its juries, refuses to enforce. Ought it not then, in justice, to withhold its censure?

BUT THE FUTURE? WHAT OF THAT?

This I have to say, that while man dwells upon the earth there will be pain, and disease, and death. It is the order of nature. Yet we are learning all the while more effective means of easing and controlling pain; we are discovering, year by year, more effective methods of preventing disease, and of battling with it when it has come; we are devising better ways of warding off epidemics; we are, with the more careful elaboration of sanitary measures, steadily lowering the average per cent of disease in population, and adding to the average length of human life. It is not all; yet it is something. Indeed, when we read the records of disease and suffering, and the death rate, of even a century or two ago, it seems much, this that has been accomplished.

AND THE QUESTION OF SCHOOLS? OF DOGMAS? OF THEORIES?—WHAT OF THESE?

Time will settle these: time, and more knowledge. As I have already said, one of the merits of rational medicine of today is, that it has learned to beware of positive dogmas and theories, and the schools which are based exclusively upon them. It has found that they are short-lived, and die out; for they are based not upon science, but upon one view of science. Then, if that view proves to be narrow, or mistaken, or false, there is nothing left, and of course they die. It has felt in its own history the evil of these things, and how they may become a clog and a bar to progress. It has learned that even today, with all the great advance which has been made in the accumulation and classification of facts, the stock is not yet sufficient for final generalization; and so has learned to work and to wait. In so varied a field, with a causation so varied, will a single general theory of disease, its causation and its management, ever be possible? It may be doubted. It certainly is not as yet. And so rational medicine, grown wiser than of old, aims to waste no time, no labor, upon problems which are as yet of necessity unsolvable. Instead, its aim now is to delve yet more deeply into the facts, and to push ever higher the standard of medical education. It feels that by this road, and by this road only, is the way to the higher truth.

And to the various schools of medical practice, schools basing themselves upon rigid dogmas and theories, it has only this to say:

"We cannot feel that you are doing the most worthy work. We cannot feel that you are best furthering the advancement of human knowledge. We can only feel that, whether you perceive it or not, you are dropping out of the current of progress; that by your premature generalization, and your rigid dogmas, you are tying your own hands in the battle. It is with no feeling of unkindness we look upon you; yet, standing as you do upon your narrower basis, we cannot recognize you as most worthy members of a liberal science.

"Only, we plead with you to weed out the low-grade institutions of learning in your ranks. Raise, as we are doing, the standard of education, and keep advancing it ever higher. If you are honest in your belief, and we do not propose to question this, you need not fear the light, and increased knowledge. Let these be the test: the dross will disappear, and whatever of good there may be will remain."

And the time will come, in that newer day, upon that higher plane of science, when schools will drop away; and no one shall say "I am of Paul, and I of Apollos," but the science of medicine shall be one: the doctor shall become doctissimus, and he shall be only a *physician,* a healer of men.

Los Angeles, April, 1888.

CONVERSATIONAL GEMS OF DR. J. P. WIDNEY*

Founder of the Los Angeles County Medical Association: At Age of Ninety-Five Still Active in Literary and Church Work

Life is a ladder. We begin at the bottom.

Many a good carpenter has been spoiled by an ambition to become an architect.

The world is constantly looking for people that can be depended upon. Hettie adds: "which causes eyestrain."

A perfect civilization will become a possibility when a perfect man has been developed.

Uneatable weeds are Nature's provision for fertilizing waste lands.

The book that will live is the book that has been lived.

Some people never grow old, and some are born old.

Civilization advances by its breakdowns.

Of all the sources of information in human history, tradition is the most imperishable.

No amount of cultivation can make genius out of a commonplace mind.

It is easier to fight an army of elephants than an army of ants.

A new word does not necessarily mean a new idea.

Reform becomes a form of hysteria. Reformers shout themselves hoarse trying to keep others quiet.

Have your wealth in yourself and not in your pocket.

No amount of cultivation will make a radish out of a turnip.

A hypocrite is a man who prays and preys.

If you would be happy, carry someone who has no legs.

The social turmoil of the world today is not a fight against capital—it is a fight against brains.

It's the continuous rain in Southern California that counts.

Birthdays, like wine, improve with age.

Education may cultivate brains—it cannot make them.

If you would be loved make yourself lovable.

There are times when words become crime.

Scholarship does not necessarily mean culture.

Culture is the ripening and mellowing of scholarship.

Pasadena Avenue is the fading remnant of a dream.

There are many good things and many good people that do not mix well.

A lump of ice will never fry a beefsteak.

The type of architecture of every country has grown out of the climatic needs of that country.

Tomorrow never comes. It is always today. Eternity is one eternal Now.

Many singers think they are singing with expression, when they are only making faces.

The way to keep your credit good is not to use it.

We cannot dress according to the calendar.

Willing shoulders always find their burden.

The surest way to get up in the world is to push other people up.

CLINICAL NOTES AND CASE REPORTS

MULTIPLE CYSTS OF BOTH LUNGS

By F. F. GUNDRUM, M.D.
AND
HAROLD ZIMMERMAN, M.D.
Sacramento

MULTIPLE thin-walled ("soap bubble") cysts of the lungs are not as rare as formerly supposed. They are, however, sufficiently uncommon that it may be worth while to present one more example of this disease.

REPORT OF CASE

H. R. Male. Single. Age 20.

Family History.—Three brothers and three sisters, all living and well. One brother died of "heart disease," as did also his father. Mother living and well.

Personal History.—Very free from all contagious maladies. He had smallpox and occasional tonsillitis.

Condition began gradually two years ago, when the patient noticed shortness of breath upon exertion, which became slowly more troublesome. He is perfectly comfortable when at rest, either sitting or lying. He coughs up a small amount (two teaspoonfuls) of "grayish yellow" sputum each morning, never bloody. All other bodily functions are normal.

The patient is well nourished, healthy-appearing young man; good color, no dyspnea; height, 71 inches; weight, 122 pounds; temperature, 99.6 at 4 p. m.; stasis good.

Head: Scalp clear; hearing good; eyes clear; pupils active; nasal passages clear; frontal sinuses and antra transilluminate well; teeth good; tonsils hypertrophic and very red (probably accounting for the slight fever).

Neck: No enlarged glands; thyroid negative.

Thorax: Well formed, well developed; vocal fremitus diminished over both lowers behind, right more than left; circumference at nipples (at rest 36, expiration 35½, inspiration 37); percussion note somewhat hyperresonant

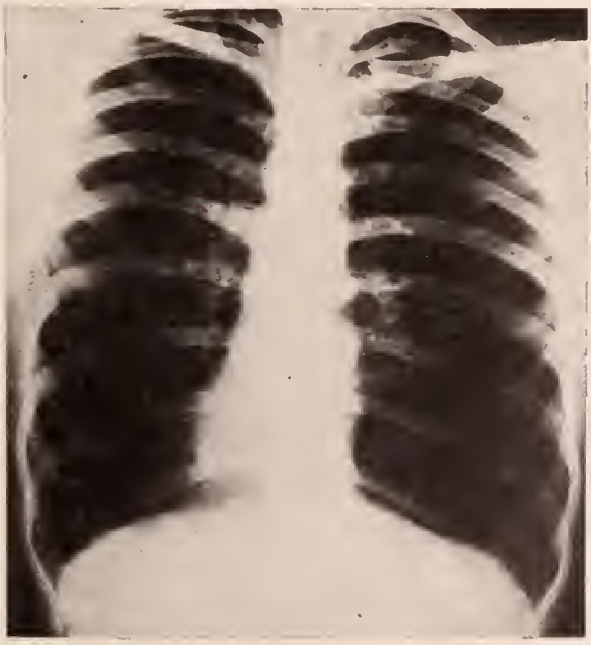

Fig. 1.—P-A view.

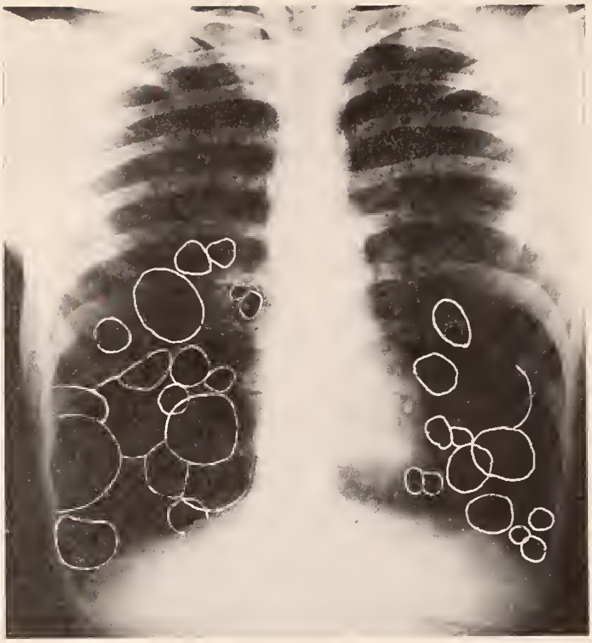

Fig. 2.—A-P view. Several of the cysts outlined with ink.

over both lungs, front as well as back; auscultation, expiratory murmur a little prolonged over the whole chest, no râles heard; voice sounds a little higher pitched over the right lower.

Heart: Dullness not increased; sounds clear and regular: pulse, 96; blood pressure, 120/100; no dilated veins; no cyanosis.

Abdomen: Flat, soft, symmetrical, no masses, no tenderness, no fluid.

Genito-urinary: Not remarkable; urine negative.

Extremities: No edema, no dilated veins, reflexes normal.

This clinical picture of empysema in a young man without previous history of asthma seemed most unusual; accordingly an x-ray film was taken with the following outcome:

"Stereoscopic chest films show a great many annular shadows in the lungs. The right lower lobe is filled with these shadows. All more or less spherical, overlapping and pressing upon one another; thin-walled, like the conglomerate shadow of a group of soap bubbles. They are also grouped around the right lung root, even in the upper lobe.

"There are a number in the left lobe; much of the lower left lobe is emphysematous, showing no lung detail. No doubt this region is filled by lesions with such thin walls that they hardly show on the films.

"This is a case of multiple, non-expansile, congenital cysts of the lungs. All connect freely with the bronchi, as none of them contain bronchial fluid or infected material.

"The upper lobes show very little involvement, and are relatively clear.

"A little secondary pleurisy over the bases."

Treatment.—The patient reported great relief of symptoms when taking small doses of ephedrin and amytal three times aday.

Yet all experience is an arch where through
Gleams that untraveled world whose margin fades
Forever and forever when I move.
—Alfred Tennyson.

A PRACTICAL LAMP FOR THE MICROSCOPE

By H. H. Parsons, M.D.
Fort McClellan, Alabama

Artificial lighting for the microscope is in almost universal use, as it is constant, uniform in intensity, and generally available.

The box type of light is useful, but requires frequent resetting; and if one wishes to use the microscope at an angle, in order to be comfortable while working, the mirror has to be readjusted for any small change in position of the microscope. In order to obviate this frequent adjustment of the mirror, I devised the light about to be described, and for the past two years have used it with much satisfaction. The light is attached to the microscope stage and moves with it, so that no matter what position the microscope is in, the light always travels with it; consequently no adjustment of light or mirror other than the original setting is needed.

The device consists of a piece of aluminum plate, 2 by 4 inches in size, and thick enough to be rigid.

A hole, 1$\frac{1}{16}$ inch in diameter, is bored or cut in the front end, 1½ inch back, through which the base of a 25 or 40 watt, round electric-light bulb is inserted, when the socket is screwed onto the light base. A ten-foot extension cord is used.

The posterior end is shaved down to allow it to fit the curve of the Abbé condenser, and a screw hole made on each side for machine screws.

Two holes are bored in the undersurface of the microscope stage, to correspond with the holes in the aluminum plate, but are not allowed to perforate the upper surface. These holes are then threaded for the type of machine screws used. The corners of the aluminum plate are rounded off. It is advisable to insulate the brass base of the electric-light bulb from the aluminum hole, and a little adhesive tape will do this. The light should fit snugly in the hole, so that it will not wobble.

For student use, this lamp could be made readily detachable.

The accompanying diagram may be used as a template in making the device.

The Station Hospital.

NARCOLEPSY

By STANLEY R. TRUMAN, M.D.
Oakland

THE recently awakened interest in this uncommon disease has prompted the reporting of a rather typical case.

REPORT OF CASE

J. D., age 30, white male, was first seen January 8, 1935, complaining of an intense and uncontrollable desire to sleep, coming on during the day.

These attacks, noticed first at about eighteen or nineteen years of age, have gradually become more intense and more frequent; and during the year previous to the first examination the attacks were so severe that at times it was necessary for him to stop driving his car, or ploughing, or to cease from other activities at periods throughout the day and take a short nap. He was also forced to give up evening social engagements because, unless there was excitement, he would soon fall asleep. The attacks come on at any time during the day, but are more likely to occur shortly after heavy noon meals, or during warm weather, or after heavy labor, or during uninteresting, quiet situations or prosy conversations.

Each attack of narcolepsy consists of a gradually increasing desire to sleep, which he cannot fight off and which culminates in what appears to resemble in all respects normal sleep. Following from five minutes to an hour or more of sleep, the young man awakens in a "sleepy" condition, but is able to go about his business, rapidly regaining his alertness. When disturbed he feels as though aroused from a normal sleep of inadequate duration, and is always cross and annoyed. He does not seem to have any disturbance of nocturnal slumber, sleeping deeply and usually from eight to nine hours. Loss of nocturnal sleep apparently increases the tendency to diurnal sleep. The patient also complained of occasional spells of weakness, but suggested no connection between these and the attacks of sleepiness. These spells of weakness (cataplexy) manifest themselves in two ways. Both are precipitated by some intense emotional response such as laughter, excitement, or anger. The first consists of an absolute inability to move. For instance, after seeing a very funny moving picture he was absolutely unable to move a muscle of his body. On this and similar occasions he has been shaken by a friend who, used to having him fall asleep, has thought him asleep. This stimulus is sufficient to recall his muscle power instantaneously. He describes the feeling as being "weak as a rag for a minute."

The other manifestation of cataplexy consists of sudden transient spells of weakness, so brief that he has never fallen. These occur during activity of some sort, such as walking, and are brought on usually by excitement, such as seeing a child falling off a fence. In this particular instance (typical of others), with his first step, on running to catch her, "his knees failed him and he almost fell, but he caught himself on the next step." He is unable to recall the age when these attacks first appeared.

The family history is negative, except that his father has always fallen asleep very readily, following meals as well as nocturnally.

He was born and has always resided in California, is actively engaged in farming, has been graduated from a university where he made a good scholastic record and showed a normal, social reaction. In childhood he had measles, mumps, whooping-cough, and chicken-pox. In 1918, at the age of fourteen, he had influenza, which apparently had no relation to the attacks of narcolepsy. He denies any venereal infection, and his blood Wassermann reaction was negative in 1925.

In 1927 and 1928 he was in automobile accidents, but in neither case was he responsible for the accident. He received head injuries, and was unconscious for a few minutes on both occasions; in the first accident there was bleeding from the right ear, and a 10 per cent reduction in hearing has resulted. These injuries did not seem to alter the course or severity of the symptoms of narcolepsy in any way.

Physical examination revealed a well-developed and nourished white male of thirty years, six feet in height, weighing 178 pounds. There were no pathologic findings, except that tendon reflexes could be obtained only on reinforcement.

The laboratory examinations showed a normal urine, hemoglobin 17 grams, and red blood cell count of 5,580,000. The white blood and differential counts were normal. The sedimentation time was over three hours, and the Kahn blood test was negative. The basal metabolic rate was plus 16.

On the basis of this typical history and negative findings, a diagnosis of narcolepsy with cataplexy was made and, following the suggestion of Doyle and Daniels,[1] the patient was given ephedrin sulphate, grain three-eighths, at 7 a. m., noon, and 4 p. m. He stated that he obtained a prompt relief of his symptoms, but that he felt nervous after the four o'clock dose; so this was discontinued after one week. For the next month he took the ephedrin regularly and felt greatly relieved, and occasionally he enjoyed an afternoon nap, but was free of the uncontrollable desire to sleep.

He was not seen again for two and one-half months, during which time he took the ephedrin sporadically. He has been able to fight off attacks of sleep while engaged in any normal activity, but if he lies down he promptly falls asleep.

Following this treatment, he took no ephedrin for one month. There has been no relapse, and he has not had to stop driving his car since first starting ephedrin. He has been able to resume evening social engagements, with the exception of bridge, "which bores him so that he cannot stay awake."

In spite of the improvement in the narcoleptic attacks, there seems to have been no change in the cataplectic phenomena.

COMMENT

This patient presents in typical form the two major manifestations of narcolepsy, the predominating symptom being the occurrence of diurnal naps as a response to an overwhelming desire to sleep, occurring after adequate sleep and rest, several times during the day. The other symptom is cataplexy, which consists of spells of weakness involving a part or the whole of the body. Frequently, as in this patient, the person does not make any connection between the two complaints, and the onset of one may precede the other by a period of months to years.

The etiology of narcolepsy is undetermined, and this patient is typical of many in the absence of any extraordinary findings. Often an interesting family history of abnormal drowsiness or actual attacks of narcolepsy has been obtained. The father of this patient shows abnormal drowsiness.

Of the other diseases showing abnormal drowsiness, syphilis, brain tumor, cerebral arteriosclerosis, hypopituitarism, diabetes mellitus, obesity, polycythemia, malnutrition, and others, this patient evidences none, except a slight increase in the blood count, and this is not of sufficient magnitude to be grouped in the class of polycythemia.

A certain number of cases of narcolepsy have followed encephalitis, and this has led some authors to consider the two conditions as related. This patient had influenza in 1918 and from the history the attack seemed typical. There is no evidence that this might have been encephalitis, and following this attack of influenza there was a period of four to five years before the symptoms of narcolepsy appeared.

---

[1] Doyle, J. B., and Daniels, L. D.: Symptomatic Treatment for Narcolepsy, J. A. M. A., 96:1370-1372 (April 25), 1935.

Patients have responded to a variety of treatments: withdrawal of spinal fluid, intrathecal introduction of air, irradiation of the hypothalamic region, psychoanalysis, and suggestion. Prior to the introduction of ephedrin sulphate, symptomatic treatment was neither satisfactory nor consistent. This drug has produced the most satisfactory results in treatment yet obtained. Some obtain prompt and apparently lasting relief, others slight or transient; but most are apparently pleased with the results obtained.

Usually the response to ephedrin affects the cataplectic tendency more than the drowsiness, but in the patient here reported the effect was just the opposite. What part suggestion has to play in this and responses to other types of treatment is hard to evaluate. However, suggestion is certainly a potent influence on these patients, and the failure of the cataplectic phenomena to respond may be due to the fact that a successful attempt was made to avoid the suggestion that the cataplexy and drowsiness were related.

SUMMARY

A typical case of narcolepsy is presented showing both drowsiness and cataplexy. The patient made a satisfactory response to treatment with ephedrin sulphate.

1904 Franklin Street.

AMEBIASIS: ITS DIAGNOSIS BY THE GENERAL PRACTITIONER

By J. F. Doughty, M.D.
Tracy

In view of the fact that from five to ten per cent of the population in California have amebiasis, it is imperative that the general practitioner be qualified to diagnose and treat this disease.

The impression has been created that such diagnosis and treatment is a highly technical and difficult procedure, which can be accomplished by only a few men in the metropolitan areas. This assumption is not warranted by the facts. Amebiasis should be suspected in the patient who presents a number of vague symptoms, usually involving the gastro-intestinal and nervous systems, and apparently without organic basis.

REPORT OF CASE

The following case history of Mr. Mc., age forty-seven, is illustrative: Six years ago he had so-called "intestinal flu," with diarrhea and abdominal distress. Since that time he has not felt very well, but has been able to work. His complaints when first observed by me, April 27, 1935, were: "Gas in abdomen, uneasiness or turmoil of intestines, sensitive belly, incomplete satisfaction following bowel movement, two mucus stools daily, rectal itching, dizziness, palpitation, sweating of palms of hands, nervousness, irritability, inability to eat beans, sweet potatoes, melons, and spinach, because they cause abdominal discomfort and gas."

Diagnosis.—The diagnosis of amebiasis can only be made by the identification of E. histolytica in the stools. The detailed description of the appearance of this parasite and its differentiation from other amebae inhabiting the intestinal tract of man, may be learned from any good book on clinical laboratory methods.[1] An excellent chart for this purpose may be found in an article by Gradwohl in the *Journal of the American Medical Association,* Vol. 102, No. 1, page 66. The cystic forms are more characteristic and more easily differentiated from the other amebae, as they have only four nuclei, as contrasted with eight in E. coli.

In the fresh specimen the protoplasm of the vegetative and of the cystic forms is seen under the low power of the microscope as highly refractile, glistening, greenish-white, transparent, ovoid or spherical bodies. The cystic form is usually about twice (15 microns) the size of a red blood cell, and the vegetative form usually two to three times (20 to 40 microns) larger than a neutrophilic leukocyte. If one is fortunate, he may see the vegetative form actively pushing out pseudopodia or containing red blood corpuscles. Morphology must be studied by the high power or oil immersion lens. A smear of the specimen may be made on a microscopic slide, fixed in Schaudinn's fluid and stained with iron hemotoxylin. This method is certainly better for prolonged study and for the differential diagnosis of the various amebae.[2] Practically, it is a long procedure and not readily done by the general practitioner unless he just fixes the slide in the Schaudinn's fluid and sends it to a laboratory for diagnosis. Here let me sound a warning—not all laboratory workers can identify E. histolytica.

The examination of the fresh stool is the method which I prefer, because it can be done by every physician and, with sufficient practice, it is quite reliable. No bismuth or mineral oil should be given previous to the examination.

Procedure in Obtaining Specimen.—To obtain the proper specimen is most important. I usually examine the first stool without any preparation, having the patient pass the stool into a paper cup at the office. One should choose the soft part of the stool and get any mucus present. One or two loopsful from different parts of the stool, is mixed with a drop of warm physiologic saline on a warmed slide. The following morning the patient is given a drastic saline purge, not allowed to eat breakfast, and told to report to the office after passing the third stool. By this time most of the food is absent from the stool, and one may get mucus. Let me *emphasize* that in the mucus can be found the typical cysts. Sometimes the patient may pass just enough mucus to soil the toilet paper, but one can get an excellent specimen from it. This mucus is placed on a slide with the loop and, if too thick, a drop of physiologic saline is added; then it is covered with a cover glass and searched for refractile protoplasm as described above.

The diagnosis is made by finding the specific protozoa. I never do less than three stool examinations, and with this method more are seldom necessary to find the organism, if it is present.

231 West Eleventh Street.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

DISORDERS OF SLEEP IN CHILDREN

I. ETIOLOGY AND TREATMENT

Oscar Reiss, M. D. (1930 Wilshire Boulevard, Los Angeles).—The causes of disturbances of sleep in children are multitudinous; and since in most instances the treatment of these disturbances consists in removal of the cause, one cannot well attempt a discussion of treatment without at least briefly reviewing etiologic factors. And inasmuch as the scope of this paper does not permit of an extensive treatise, I will not attempt to do much more than classify in outline the various factors causing sleeplessness in children.

1. *Constitutional Neuropathy.*—Under this heading may be grouped those infants and children who have great difficulty in relaxing while awake, who do not fall asleep easily, who toss around considerably after falling asleep, and who are easily aroused by even trivial environmental stimuli. They manifest a tendency to tetany, spasmophilia and rickets, and the accompanying calcium deficiency, and are easily thrown into convulsions.

The treatment for this group consists in active calcium therapy to the point of establishing the necessary balance. At the same time attention should be given to the establishment of an environment free from disturbing factors.

2. *Sleep Disturbances Accompanying Disease.* One might include in this category practically the entire list of diseases with which children become afflicted, since each one of them may produce interference with sleep. Painful conditions should be considered first. Otitis media, especially in infancy, may show no other symptoms than fever and disturbed sleep, restlessness and wakefulness being the result of earache, which the little one cannot localize. The sleep of infants is also commonly disturbed by the pain of colic and intestinal disturbances, by hunger, by teething, and also because of eczema or furunculosis. In older children, renal colic, rheumatic fever, and the cardiopathies are potent disturbers of sleep.

Respiratory difficulties, whether due to nasal obstruction with consequent mouth breathing, or to the dyspnea of asthma, or to bronchial irritation of pneumonia or whooping-cough, with frequent coughing spells, mitigate against undisturbed sleep.

The ushering in of nearly all of the infectious diseases of childhood is usually evidenced by disturbed sleep, as one of the initial symptoms.

For those conditions where pain is interfering with sleep, the removal of the cause of the pain or discomfort is of primary importance; the child so often falls asleep immediately following paracentesis of a bulging eardrum. Often narcotics are necessary, codein being very effective. In the management of any of the above-mentioned conditions, attention to the comfort of the patient is important and conducive to sleep. Tepid baths in febrile conditions, and antipyretics in prolonged fever are helpful. The barbiturates may be given freely, especially when there is considerable restlessness.

3. *Faulty Physical Hygiene.*—The character of environmental conditions conducive to sleep seems to be well-known to physicians and to many laymen; nevertheless, one observes so many infractions of the rules of hygiene that it may not be amiss to mention the most flagrant ones. Troubled sleep or failure to fall asleep may be due to uncomfortable clothing, tight clothing, too many clothes, too much covering, and pressure of safety-pins. It may be due to an overheated bedroom, or one that is too cold, or to the lack of quiet and darkness. Some infants with very sensitive skin cannot sleep in a soiled or wet diaper. Quite obviously, the treatment must be directed toward the education of the parents in rules of hygiene. Too much stress cannot be laid on the desirability of having each child in a room by itself (certainly in its own bed), the room to be well ventilated and dark when the child is put to sleep, his night clothes to be light and comfortable, and the bed covers to be light in weight and sufficient in amount to meet the varying climatic conditions.

4. *Faulty Mental Hygiene.*—Under this grouping we shall list various forms of faulty management of children, which tend to upset them mentally or emotionally to the point of interfering with restful sleep.

In infancy, faulty sleeping habits are easily established and difficult to overcome. They should never be allowed to develop. The most common faults are overanxiety on the part of the mother, which results in the baby being picked up constantly on his slightest outcry. Often a pacifier is introduced, either into the mouth in the form of a nipple, or as a comforting plaything like a favorite toy animal or doll or a little quilt. Or perchance there may be a grandmother or an old family nurse to rock the baby to sleep. The eventual breaking of these habits always means a period of great strain for the child, the family, and the doctor.

To insure normal, peaceful sleep for children beyond the stage of infancy requires a thoughtful viewpoint on the part of the parents, and an understanding of the nature of each individual child.

Unfortunately many parents are completely ignorant of the fact that the emotional experiences and mental perplexities that befall a child during the day may have an untoward effect upon its ability to fall into peaceful slumber. Overstimulation, as represented by a too ambitious school program, too many extracurricula activities (dancing, music lessons, etc.), premature and untimely participation in social affairs and pleasures of the adult, unsuitable movies and radio programs, are not conducive to restful sleep. Nor is unreasonable or unjust discipline, which is often imposed by a parent who has undergone some vexatious experience, and is "taking it out" on the child. The child of sensitive nature is especially upset by such treatment.

Emotional shocks, such as are often produced by fright or the witnessing of some gruesome spectacle, are often the basis for some of the more serious disorders of sleep, such as night terrors. Many other factors could be recounted, but those mentioned above should suffice to emphasize the damaging effect of mismanagement.

Treatment

Treatment for the relief of disturbances of sleep caused by faulty mental hygiene obviously must be directed at the parents, who are usually directly or indirectly responsible. The therapy is educational in nature. One must patiently and painstakingly point out how in each instance the particular form of mismanagement has been responsible for the problem that has arisen, and that its cure can be brought about, not by the administration of drugs, but only by the institution of a thoughtful and intelligent program for the child.

* * *

II. FATIGUE AS A CAUSE OF SLEEPLESSNESS

Henry E. Stafford, M.D. (242 Moss Avenue, Oakland).—Fatigue is the most common cause of a disturbed sleep pattern in childhood. It is well said that the tired child is the one who does not sleep; not the one who is getting too much rest. Sleeplessness and fatigue too often form a vicious cycle. The tired, irritable child with diminished appetite loses his ability to take advantage of an adequate amount of rest; insufficient sleep in turn results in fatigue. Superficially there would seem to be little difficulty in solving the problem by placing a child at rest for a sufficient length of time. Practically this is at best only a temporary expedient. Fatigue, as well as sleeplessness, is only a symptom. It is illogical to attempt the explanation of one symptom in terms of another. Until we have determined the cause of fatigue and corrected it, our problem remains unsolved. Consequently, any discussion of sleeplessness in childhood must be based upon an analysis of the underlying factors which produced fatigue.

A faulty sleep pattern may be established early in life through faulty habit formation. The growing infant needs regularity. The irregularity of, or variation in the length of rest period promptly becomes a habit, and the loss of much needed rest ultimately results in fatigue. In this way the first link in the vicious cycle may be welded in the first few months of life. When the child grows older, objections to the afternoon nap are invariably raised too early in every household. There is no way to make a child sleep, but no rapidly growing individual should be excused from a mid-afternoon rest until the age of five, and longer in some children who tire easily. Such insistence is not often easy, but it may mean the difference between an irritable, restless child, and the one who lives a well-ordered happy life. Closely allied with the tendency to early elimination of the nap time, is the postponement of bed time at night. The late hour of a father's homecoming is often responsible. His desire to see and play with the small offspring too often forms the necessary wedge for the delayed bed time. The one or more hours of needed rest are not made up in the morning; the time of arising for the child remains unchanged. Valuable rest is lost.

Selection of the place for sleep is as important as regularity. In an effort to obtain "fresh air," many infants are put to rest on a noisy porch or in a glaring garden. In either surrounding, complete relaxation is impossible. An airy, darkened room furnishes sufficient ventilation and tends to promote rest of necessary duration. Many children are allowed to play in the bed or pen in which they take their nap or sleep at night. Any infant whose routine of living is not yet established is easily confused. Consequently, when he is put down to rest in surroundings associated in his mind with play, confusion results. More often than not, activity, either physical or mental, continues until sheer exhaustion drives him to sleep, and he slumps into some unnatural position to be found later uncovered and chilled. By the same token toys should never be placed in bed with a child. Too many covers, soft mattresses sloping to a hollow in the center of the bed, and pillows of all sizes and shapes play their part in disturbing the rest of the small infant and the runabout child. Too commonly parents will finally confess that their child is taken to bed with some older member of the household. This usually occurs toward morning, and often begins quite innocently during an illness or following some unusual event in the home. But it need happen only once or twice, and the child automatically awakens in order to move into another bed. In the same way habitual thumb suckers or blanket twisters arouse for varying lengths of time to practice their individual habit. Such incidents of mismanaged routine may seem trivial and even ridiculous. However, they are means of interfering with satisfactory rest; and so lead to fatigue and ultimately to sleeplessness.

Infections play an equally major rôle in the production of fatigue. A child competently supervised is kept in bed following an acute infection until all signs of fatigue have disappeared. Less commonly is it realized that there may be a connection between a chronic focus of infection and disturbed rest. Diseased tonsils and adenoids, infected sinuses, the invasion of the urinary tract by colon bacilli, enlargement of the hilum lymph nodes, tubercular or nonspecific thickening of the lung parenchyma result in symptoms similar to those of overexertion. Consequently the control of such chronic infections transforms the whiny, overexcited, restless child into a quiet, contented individual with a normal sleep pattern. It is very difficult for many parents to realize that there may be a connection between infection and sleeplessness.

Associated with, and often combined with infection are allergic phenomena. Hypersensitiveness to any allergen may produce fatigue and, consequently, sleeplessness in one of two ways. First, the mechanical blocking of the upper respiratory passages by the boggy, swollen mucous membrane of allergic rhinitis may awaken a child because of the resultant difficulty in breathing. Secondly, some of the less evident phases of increased sensitivity as, for example, the abdominal allergies may produce a sufficient amount of discomfort to interfere with rest. Reactions bordering on the spectacular result in some children when an offending protein is removed from their diet, or an irritating inhalant is eliminated from their surroundings and disturbed rest is replaced by complete relaxation.

Certain tired, sleepless children are described as "nervous" by parents, teachers, and nurses. The term itself is inadequate and inaccurate, largely because it connotes an inability of understanding and control. In reality the whiny, incorrigible child, given to frequent tantrums, has as a physical basis a tired central nervous system from which originate incoördinated stimuli. Among the common and neglected causes of such fatigue are ocular refractive errors. It is a pertinent reason why every child should have a routine eye examination by a competent oculist at the beginning of school training. In no other way can any but the glaring errors in sight be discovered and corrected. The eradication of such defects tends to reduce fatigue, diminish overstimulation and, incidentally, sleeplessness.

Imbalance of the glands of internal secretion may play a part in the production of fatigue. Paramount among the better understood glandular conditions predisposing to fatigue is hyperthyroidism. It has become comparatively easy to diagnose the undernourished hyperactive individual with a high metabolic rate due to oversecretion of thyroid hormone. Many clinicians fail to realize that the same clinical picture, but with a low metabolic rate, is also found in hypothyroidism. Previous to the observations on skeletal development in relation to thyroid activity, it was impossible to differentiate between increased or diminished activity of the thyroid in children under the age of eight years. Aside from the difficulties incident to the actual tests, the normal standards of basal metabolic rates below this age are inaccurate. Undoubtedly, as we learn more concerning the interrelationships between other glands of internal secretion many of the problems now poorly understood will become clear-cut diagnoses.

Fatigue posture, exemplified by underdeveloped rhomboids, sway back, prominent abdomen and sagging head is usually effect rather than cause. Consequently, muscular training necessary to correct such posture is usually insufficient in itself to permanently diminish fatigue. Conversely, the elimination of the underlying factors of faulty posture without the training in proper muscular balance will leave the problem only half-solved.

To summarize: disturbed sleep is, as a rule, a symptom of fatigue which in turn is dependent on a variety of underlying causes. As such, sleeplessness becomes a real diagnostic problem. It cannot be solved by the simple expedient of placing the tired child at rest for a period of time. The solution only becomes clear following a complete history and physical examination fortified with indicated laboratory data. In no other way can the relative importance of chronic foci of infection, glandular imbalance, early habit formation, allergy and congenital somatic defects, such as optical refractive errors, be evaluated.

* * *

III. SLEEP DISTURBANCES IN CHILDREN

Guy L. Bliss, M. D. (1723 East Third Street, Long Beach).—Every child inherits his own individual sleep pattern. This pattern is disturbed, and then only temporarily, by strong sensory impressions. In this discussion we are concerned only with the sleep disturbances of children who are both mentally and physically normal. During sleep the receptivity of the individual to sensory stimulation is greatly diminished, but motor activity continues in an apparently automatic manner. It is conceded that the depth of the sleep is inversely proportional to the amount of sleep movement; hence, any factor causing excessive movements during sleep leads to sleep disorder. While there are many factors causing sleep disorders in children, I wish to mention only four. In this we are offering nothing new. These simple, every-day factors which cause so much disturbance in our children at night are such common knowledge among pediatricians, we assume them to be common knowledge among the parents, and accordingly fail to emphasize them.

1. *Weather Temperatures on the Child.* — It matters not whether it is the high temperature of a torrid summer night, or a poorly ventilated room, or an artificially overheated room, or too many blankets on the bed, the end-results are the same. The child's motor activity is tremendously increased. He is continually thrashing and crawling out from under the bed covers, in spite of the many patented gadgets and paraphernalia to restrict him in the hot bed of discomfort. Parents are bound by the time-worn prejudices that a child might take cold if he is not covered heavily at night. The consensus of opinion, that no child gets sick or lowers its resistance by getting cold, is a fact which we often fail to make clear to the parents. The amount of heat and covers that any child needs is a very personal individual requirement. We should instruct the parents how to determine the amount of heat and covers best suited to the individual child.

2. *Heavy Meals.*—At night, within certain definite limits, it does not matter so much what kinds of foods are taken, but the size of the meal is very important. A heavy meal at night, in the majority of children, is prone to cause not only excessive

motor activity, but terrifying dreams, crying out in sleep, and a constant turning in bed. The habit of a heavy meal at noon and a light meal at night, just enough to meet the child's caloric requirements, will help to relieve one of the child's most common causes of sleep disorder.

3. *Bright Lights.* — How many times we are called to a home to see why Johnny will not take a nap. We find him in bed, in a room with a south or west exposure, with the window shades up and the curtains drawn aside to let in all the sun and light possible. The mother realizes the importance of sun and is too literal and enthusiastic in her attempt to give her boy both sunlight and a nap at the same time. A darkened room will give Johnny an autosuggestion of night, and he easily falls into a refreshing slumber.

4. *Noise.*—It is so silly that it seems asinine to mention, but legion are the mothers who expect Johnny to take a nap in a room where the blatant rasping voice of an advertiser rents the air, or they expect him to sleep in a room on the side of the home where a street-car squeals and rumbles by every ten minutes.

The above mentioned factors are some of those causing disorders of sleep, and have been common knowledge among all clinicians for years. Now the laboratory has come to our assistance and corroborated our observations with an electric recording device, called a hypnograph. Dr. Glenville Giddings, with the hypnograph, has shown that some of the factors mentioned causing excessive motor movement during sleep are positive influences in causing disorders of sleep in normal children.

The function of the pediatrician in preventive medicine is that of a teacher. Our problem is to overcome the ignorances, prejudices and superstitions of the average parent, and to convey to them practical ideas couched in sufficiently common horse sense to be within the mental grasp of all.

Optometry: Corporate Practice of Optometry Illegal in Arizona; Injunction to Restrain Practice.—The Funk Jewelry Company, a corporation, employed a licensed optometrist to examine eyes and to prescribe glasses. The state of Arizona, on the relation of the attorney general, instituted action to enjoin the corporation from practicing optometry. From an adverse judgment in the trial court, the corporation appealed to the Supreme Court of Arizona.

The optometry practice act, said the court, prescribes certain qualifications to be possessed by applicants for licenses to practice optometry. These qualifications necessarily exclude a corporation from practice. It cannot qualify. It does not possess the necessary moral and intellectual qualities. The corporation, therefore, when it employed a registered optometrist as a part of its business to examine eyes and to prescribe glasses, violated the optometry act. It was apparently contended, however, that even though the corporate practice of optometry was illegal, an injunction would not lie to restrain that practice. The optometry act, observed the court, prescribes no punishment for those who violate its provisions. Consequently, the ordinary criminal sanctions, such as fine and imprisonment, are not available to prevent continued violations of the act. Unless the writ of injunction is available, there is available no remedy to enforce the act. Furthermore, the court continued, while the civil process of injunction may not ordinarily be used to prohibit persons from committing a crime, where the crime is a public nuisance or affects the interests of the state, injunctions will lie. *State* v. *Smith* (Ariz.), 29 P. (2d) 718, 31 P. (2d) 102, 92 A. L. R. 168. The tendency is to grant injunctions to prevent unlicensed persons from practicing the professions. If the present action, said the court, had been brought by the state board of optometry or by members of the optometry profession, there would be no question of their right to maintain the action, in view of the trend of judicial opinion. The present action, however, was brought by the state, on the relation of the attorney general. The optometry act, continued the court, was passed for the general welfare of the people of the state. Its purpose is to protect the health of the people, and, while the state may not have any pecuniary interest in the enforcement of the act, it has a very much higher interest, and that is in the protection of the health and well being of its people. That being the case, it seemed to the court that the state, acting through the attorney general, could lawfully apply to the courts to exercise their equity powers to enjoin violations of the act.

The corporation apparently further contended that the state board of optometry had entered into some kind of an agreement with the licensed optometrist whereby the board agreed that the optometrist might render the services for which he was employed for a limited length of time. Such an agreement, the court said, would not have the effect of suspending the requirements of the optometry act. Furthermore, the agreement did not purport to authorize the corporation to practice optometry, and if it had, the agreement would have been void.

The judgment of the trial court, granting the injunction, was therefore affirmed. (*Funk Jewelry Co.* v. *State ex rel. La Prade* (Ariz.), 50 P. (2d) 945.)—*Medicolegal Abstract, Journal of the American Medical Association.*

Compensation of Physicians: Liability of Third Person for Medical Services.—The plaintiff, a physician, sued the defendant to obtain payment for medical services rendered a Negro employee of the defendant. The Negro, suffering from a gun-shot wound, was taken to a hospital owned and operated by the plaintiff. Immediately thereafter the defendant came to the hospital and, according to the plaintiff, said: "If you will go ahead and take care of the case, I will pay the bill." The testimony of several witnesses tended to corroborate the plaintiff. The defendant, however, denied that he had made the promise just noted and, from a judgment for the plaintiff, he appealed to the Supreme Court of Oklahoma.

The Supreme Court, however, believed that the evidence reasonably tended to support the verdict of the jury. In *May* v. *Roberts*, 28 Okla. 619, 115 P. 771, relied on by the court in the present case, the plaintiff, a physician, brought suit for services rendered the wife of the defendant's tenant. The defendant had requested the physician to visit the tenant's wife and told him that he would see that the bill was paid. Such evidence was held to be competent and material and to establish a primary liability not within the statute of frauds. Finding no error in the record in the present case, the Supreme Court affirmed the judgment in favor of the physician. (*Gloeckler* v. *Weedn* (Okla.), 50 P. (2d) 634.)—*Medicolegal Abstract, Journal of the American Medical Association.*

Workmen's Compensation Acts: Death from Sunstroke.—Death from exposure to the elements, including the heat of the summer and the cold of the winter, said the Supreme Court of Iowa, is not compensable if the hazard is the same to which the general public is exposed. For compensation to be recoverable for death from sunstroke, the deceased must have been subjected to a greater hazard from heat than that to which the public generally in that locality was subjected. This distinction is recognized by all the authorities. Compensation was denied in this case. (*Wax* v. *Des Moines Asphalt Paving Corporation* (Iowa), 263 N. W. 333.)—*Medicolegal Abstract, Journal of the American Medical Association.*

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section (Adv. pages 2, 4 and 6).

CALIFORNIA MEDICAL ASSOCIATION

EDWARD M. PALLETTE	President
HOWARD MORROW	President-Elect
FREDERICK C. WARNSHUIS	Secretary-Treasurer

1936 ANNUAL SESSION: CORONADO
MAY 25-29, 1936

PROCEEDINGS OF THE FIRST GENERAL MEETING

Monday Morning, May 25, 1936

President Peers: Ladies and Gentlemen, Members of the California Medical Association and of the Woman's Auxiliary: As president of the California Medical Association, it is my official duty and pleasure to call to order the first general session of the sixty-fifth annual convention.

At this time it gives me pleasure to present Dr. Benjamin F. Eager, president of the San Diego County Medical Society, who will give the address of welcome on behalf of the San Diego County Medical Society, our host on this occasion. Ladies and gentlemen, Doctor Eager. (Applause.)

* * *

Doctor Eager: President Peers, Distinguished Guests, Officers and Fellow Members of the California Medical Association: It is the pleasure of the San Diego County Medical Society to be host to this convention. Many committees have worked for many months in order that your splendid program may go through with a maximum of efficiency and a minimum of inconvenience. Our distinguished guest speakers, together with those who make up the rest of the program, give assurance of rare pleasure and profit to all those attending, the only difficulty being that we are unable to listen to two papers of particular interest at the same time. This year, more than ever before, all of our component societies are looking forward with especial interest to the work of the House of Delegates and of the Council in handling certain difficult problems, some of which are more or less peculiar to California. Doctor Shoulder of Tennessee, Assistant Speaker of the House of Delegates of the American Medical Association, spoke ably and exhaustively at the Minnesota state meeting early this month, with the sole purpose of academically instructing the members on the evils of state medicine. We of California are faced with more immediate and more concrete needs for action. Our local society has already voted for coöperation with the state in the matter of hospital insurance, and, of course, may be counted upon for a share in the handling of the campaign against the antivivisection initiative, which is already on the ballot, and the increasingly difficult county hospital problems, and the basic science law, which is coming up in 1937. In this connection, I might say that several of us had the pleasure of meeting our editor, Doctor Kress, here some months ago, and we nearly wore him out with questions and arguments on this matter. . . .

And now for the varied and often strange interludes of relaxation and entertainment. We of San Diego can offer such a variety that we can say with the old lady who kissed the cow, "Every fellow to his notion." Besides golfing and bathing, which we had better say comes every day—yesterday and tomorrow—we have a distinctive sport, sword-fishing, which is fully equal to the famous tarpon fishing of Florida, and, incidentally, for the benefit of the fishermen, the game yellowtail is running beautifully right at the present time. Of course, you will want to visit the Hall of Medical Sciences and the other attractions at our Exposition, even though Sally Rand has been replaced by Ben Bernie. And for one of our outstanding attractions we have our military units: the Naval Hospital, which is probably the finest in the country; the Naval Training Station; the Marine Base; Fort Rosecrans; and the flying units of North Island. All of these can best be explained to you by Captain Porter, who is Commanding Officer here at the Naval Hospital.

The Mayor of San Diego yesterday tendered his best wishes to all the visiting doctors and, in contradistinction to Winchell, the keys to the city. The Chief of Police of Coronado, in a little heart-to-heart talk which we started, also tendered his very best coöperation and the best keys he had. Thank you. (Applause.)

The President: Thank you, Doctor Eager. I notice that Doctor Eager, like myself, is also a student of Rabelais, because those who have read Rabelais remember how he mentioned the old lady who kissed the cow. I am going to refer to François Rabelais a little later myself.

The medical profession has always been proud of the service that has been rendered by members affiliated with the Army and the Navy of the United States, and the United States Public Health Service. These members, in their respective services, have made many contributions to the advancement of scientific medicine and, in recognition of this service, the California Medical Association deems it a privilege to present the Commanding Officer, F. V. Porter, of the Eleventh Naval District. Ladies and Gentlemen, Captain Porter. (Applause.)

* * *

Captain Porter: Mr. President and Members of the California State Medical Society, Distinguished Guests: I think your president slightly misled you as to my position. I am simply Commanding Officer of the Naval Hospital, which is only one of quite a few units in the San Diego vicinity. You see, there are the training station, the air station, the receiving station, and various other units. Although it is commonplace and quite superfluous to say so, I feel very highly honored to be invited to this platform, and I want to express my thanks to your president, speaking not only for myself, but for the Navy and the Medical Corps, for his courtesy in extending to us the privilege of attending your meetings. San Diego is very largely a navy town, so I think it is not improper that I welcome to San Diego, on behalf of the Navy, the out-of-town members of your society. More particularly on behalf of the Commandant of this district, I want to extend a cordial welcome to them to visit the naval establishments here, and to all of you I extend a most cordial invitation to visit our Navy's one-thousand-bed hospital in San Diego. Both here and in the San Diego, San Pedro, and Long Beach areas, the Navy medical groups and the local medical groups make many contacts with each other, and I am happy to be able to say that these contacts are all friendly and cordial. Each group has much to offer the other, with mutual profit and satisfaction. However diverse may be our lives and our ways of livelihood, we have at least one great aim in common, the mission of caring for the sick and equipping ourselves; that is, equipping our minds, our hands, our stock of tools, and our materials, to carry out this mission always better than we have ever done in the past. We in the Navy Medical Corps in San Diego esteem it a distinct privilege and opportunity to be able to attend the local medical society meetings and clinics in this area. We are happy to have local men attend our surgical and other clinics, and our weekly staff conferences at the hospital, and we would be more pleased if this exchange of meetings, attendance, consultation and visits, all of which amount to exchange of ideas, could become much more extensive than it has been in the past. The Naval Hospital here is the largest hospital this side of Los Angeles. It always has on hand a wealth of clinical material, often including diseases contracted in tropical and distant places, diseases seldom seen by civilian physicians. If some of you can find time to go with us on our ward rounds or into our work rooms, we may be able to show you some things, and I am certain that you could tell and show us many things. Again I want to give your society the Navy's welcome to San Diego, and say that we are glad that your meeting this year is close enough to San Diego so that we of the Navy Medical Corps may meet with and make some acquaintance with you. (Applause.)

The President: Thank you very much, Captain Porter, for your cordial welcome.

Doctor Warnshuis, secretary of the California Medical Association, has a few announcements to make.

* * *

The Secretary: Mr. President, Distinguished Guests, Members of the California Medical Association and Their Friends: You are all experiencing the efficiency of the profession of San Diego in the splendid arrangements that they have made for our comfort and for the success of this meeting. Their efficiency has extended so far that they have used their president in making his welcoming address as a source of some of the announcements of the secretary in order to fill out the time that was allotted to him, so I will not take much time in making my announcements. Along late last fall the management of the San Diego Exposition, together with representatives of the San Diego County Medical Society, approached the officers and the Council of the California Medical Association, requesting them to assume the responsibility for a medical hall of science at San Diego. The San Diego County Medical Society, through a very efficient committee headed by Dr. Lyell Kinney, with Doctor Geistweit as secretary, has presented to the people of this nation (and I say "people of this nation" advisedly, because they are visiting us here) a most outstanding demonstration of what medical science has and holds for the public welfare. I am sure that I have not the words to express the appreciation that should be felt by every member of our Association for this educational program that is being conducted now at the Fair, and which will continue until the ninth day of September. As a result of their activity, we have had tendered to us the control, supervision and censorship of the Medical Hall of Sciences at the San Francisco Fair in 1939; and the San Francisco Chamber of Commerce did not ask me to make that announcement. So it is the very earnest desire of the Council and the officers of this Association, and also the members of the San Diego County Medical Society, that every one of our members take the opportunity to go to this Exposition, and especially to see this medical exhibit in the Hall of Science.

The very efficient Captain and Commanding Officer of the Naval Hospital has also trespassed upon the secretary's announcements, and therefore I will not have to say very much in supplementing what he has extended to you—the most cordial invitation of the Navy Department, especially the Navy Medical Department; and may I say, also, that Surgeon-General Rossiter supplemented that invitation at Kansas City two weeks ago.

The president's dinner will be held tomorrow evening in the main dining room at 7:15 p. m. There will be a dinner that will last probably until about nine o'clock, when we will adjourn to this room, where we will attempt to entertain you for one hour upon this platform with some very talented representatives of the San Diego County Medical Society, and after their entertainment the floor will be cleared and those who wish to do so may dance.

The House of Delegates convenes in this room at 7:30 this evening, and the Council meets at two o'clock this afternoon.

I am sure that this should serve as a very adequate and fitting introduction to the wonderful address that you are now going to hear from your president, Doctor Peers. Now it is my official duty to present to you the president of the California Medical Association, who will read his presidential address.

(President Peers read his presidential address.*)

At its conclusion the audience stood and applauded.

* * *

The President: Thank you very much. This is just another evidence of how kind everybody has been to me through the whole year.

It is now my duty and pleasure to introduce one of our guest speakers from without the state. As a tuberculosis worker for many years, it is a very great pleasure to me to have on our program this morning, and to be able to introduce, one of not only national but international reputation in tuberculosis work. Doctor Singer is going to speak to us this morning on "Newer Methods in the Treatment of Pulmonary Tuberculosis." It is a pleasure to introduce Jacob J. Singer, M. D., associate professor of clinical medicine, Washington University School of Medicine, St. Louis. (Applause.)

* * *

(Doctor Singer read a paper on "Newer Methods in the Treatment of Pulmonary Tuberculosis." †)

The President: Thank you, Doctor Singer. Those of you who do not know him as so many of us on the Coast do, understand why I spoke of him as a distinguished student of tuberculosis, nationally and internationally known. I think that was a wonderful address and we appreciate it very much. Doctor Singer has said that if anyone wishes to come up and talk with him after this session is concluded, he will be happy to have them do so.

The meeting was adjourned by the president.

HOUSE OF DELEGATES MINUTES

Sixty-Fifth Annual Session—California Medical Association

*Minutes** of the meetings of May 25 and 27, 1936: Hotel del Coronado, Coronado, California.*

FIRST MEETING

Monday Evening, May 25, 1936

The first meeting of the House of Delegates of the California Medical Association was convened in the Ballroom, Hotel del Coronado, Coronado, California, on Monday, May 25, 1936, at 8:15 p. m., with the Speaker, William W. Roblee of Riverside presiding.

The Speaker: The House will be in order. The Speaker has appointed a Credentials Committee consisting of Doctors Askey, Dexter Ball, and Kelly Canelo. We will hear the preliminary report of that committee at this time.

Dr. Askey: Mr. Speaker, the report of the Credentials Committee is not complete at this time. There are ninety-nine members registered so far, which constitute a quorum.

The Speaker: If there are no objections, the preliminary report of the Credentials Committee will be accepted and the delegates will be seated. The Speaker hears no objections. It is so ordered. Mr. Secretary, call the roll.

The Secretary: Mr. Speaker, I hold in my hand the signed attendance slips of ninety-nine accredited delegates. I suggest that these attendance slips be considered the roll call of the House for its first session.

The Speaker: If there are no objections, that order will hold. A quorum of accredited delegates being present, the provisions of the Constitution and By-laws having been complied with, I now declare the House duly constituted and open for business.

Appointment of Reference Committees

Reference Committee No. 1 on "Reports of Officers and Committees, Both Regular and Special"—Eric Larson (chairman), Alfred Phillips, and Nathan Hale.

Reference Committee No. 2 on "New and Miscellaneous Business and Resolutions"—Daniel Crosby (chairman), Morton Gibbons, Sr., and Ben O. Adams.

---

* The address of President Robert Peers of Colfax was printed in the June issue of California and Western Medicine, page 464.

† Doctor Singer's paper will appear in a later issue of California and Western Medicine.

** Original minutes as taken by stenographers are on file in the central office of the Association. Because of lack of space in the official journal, some portions are not here printed.

Will the chairmen of the committees decide upon a place and time of meeting so that it can be announced a little later in the proceedings?

Introduction of President Peers

The Speaker: I think if it were necessary for us to characterize in one phrase the administration that is just closing, we could say that it has been a friendly one. President Peers has gone about the state to the farthest corners, radiating good cheer and friendship wherever he went. His wife characterized him one time in my presence in a very apt way. She said, "My husband never takes the trouble to dislike any man." I think that is true. (Applause.) Doctor Peers' friendly contacts over this state this year have meant much to organized medicine. Not infrequently he speaks of saying things "to the boys." We are all his boys. President Peers, you may now have a few minutes to talk informally to your boys in a way that you could not do in the formal meeting this morning. Gentlemen of the House, your President. (Applause.)

Remarks by President Robert A. Peers

The President: Mr. Speaker and Members of the House: I hope the speaker will allow me to talk to my girls as well as to my boys. There are quite a few of the girls here and some of them are delegates. I did not expect to talk to you tonight. I thought this morning that I had already sung my "swan song." So all I want to say to you is that I have had a wonderful time. I told you that before, and I tell it to you again. I have had a wonderful time because I have had such perfect coöperation from every member of the Council, every one of the general officers, from the presidents, secretaries and other officers of the county societies, and from the men and women of the county societies. I have had a splendid time because of this coöperation, but I will feel a sense of relief, of course, when Wednesday night rolls around and I can turn the burden over onto Eddie Pallette's shoulders. There will be a certain relief about that, but you know I am going to miss a lot of trips. I have had a wonderful time because you men and women throughout the state have made it so for me, and I thank you very much. (Applause.)

The Speaker: Mrs. Peers told me to tell you that she was having a nice sign painted saying, "Welcome home."

A little later in the evening, opportunity will be afforded those who wish to introduce resolutions or amendments to the Constitution and By-laws. If you will have those ready, it will save some time and confusion.

The next item on the docket is the report of the Council. The chair recognizes Dr. T. Henshaw Kelly, chairman of the Council. (Applause.)

Report of the Council

Doctor Kelly: To the Speaker and House of Delegates, Greetings. There is hereby submitted to you, and through your members to the membership at large, this annual report of the Council.

1. *Foreword*—Inasmuch as all the minutes of the Council meetings have been published from time to time during the year and constitute part of this report, the Council limits this annual report to general summarization, and certain comments and recommendations that it feels should receive special consideration by this House of Delegates.

2. *Finances.*—The certified order of the Association's financial transactions and resources is submitted as Appendix A to this report. Your Council directs attention to an operating loss for the year of $26,968.20. This loss in operations and resources resulted from very implicit and unlimited action by, and instructions from the House of Delegates, and arose from the following extraordinary expenditures: The Committee of Five, $17,278.16; the Committee of Six, which dealt with the matter of the Senate Bill 454 in the 1935 Legislature, $4,736.19; and expenses connected with legislation, $10,921.10. The Council calls attention to the fact that the resources of the Association would have been further depleted to the extent of $12,641.98 had it not been for actual savings made in administrative costs and authorized expenditures for other activities of the Association, by the careful supervision and the experienced advice and work of the secretary-treasurer. This amount was actually saved by him through studied purchasing, extra work, and careful attention to detail in the work of the Association in 1935. Delegates are informed that a poll of the members overwhelmingly favored an expenditure of approximately $35,000 to obtain the enactment of a qualifying certificate law by iniative legislation. This poll was taken before the decision of the Supreme Court upholding the law passed by the 1935 Legislature, requiring every voter to reregister in 1936. After this decision, expert opinion was against risking the initative this year, because of the limited time left to obtain the signatures and the danger of having too many of those obtained declared illegal. Therefore, the Council is preparing for the 1938 general election and the committee on the basic science act, or the qualifying certificate act, will further report to the House of Delegates through its chairman, Dr. George H. Kress. From information transmitted by the Committee on Public Policy and Legislation, it is anticipated that legislation in the interest of public welfare, and of interest to all members will be sought during the coming election and in the session of the 1937 Legislature. Additional funds will be necessary to oppose untoward legislation. The House of Delegates is further advised that pending court procedures in matters that concern the profession and its future will demand representation and added expense. In view of these pending activities and the expenses that they incur, the Council recommends that careful and thoughtful consideration be given to devising means to meet these problems. The Council requests that the delegates determine whether funds be obtained by increasing the annual membership dues, or by the levying of a membership assessment. Your consideration should make it apparent to every member that an increase in income is imperative for the Association's solvency, as well as to enable it to function unhampered to the best interest of individual members and the future welfare of the profession of this state. Remembering that the dues are set annually by the House of Delegates, and that the Legislature meets in 1937 after the general election in November, 1936—at which time it is very likely that the county hospital initiative will be on the ballot—the Council recommends that the House of Delegates set the dues for 1937 at $15 per active member.

3. *Membership.*—The secretary's annual report records a total of 5,402 active members on January 1, 1936. It is estimated that this represents 83⅓ per cent of the qualified desirable physicians and surgeons of the state. This conclusively establishes that our Association is the representative body of the licensed physicians and surgeons of the state, and, as such, that it is the mouthpiece of the profession, authorized to speak for it in matters that concern its interest. There are, it is estimated, about one thousand physicians eligible for membership not now affiliated. The Council urges that every county society make a determined attempt to obtain the affiliation of all eligible and desirable physicians.

4. *Council Meetings.*—During the year the Council has held six meetings. Its minutes have been published in full. The Executive Committee has held three meetings and its minutes have also been published. The Council also initiated a County Secretaries' Conference. The full report of that conference, which will now be an annual function, was published in the March issue of California and Western Medicine. Individual reports of councilors will be found in the Pre-Convention Bulletin. They represent a more intimate insight into the activities of each councilor district. In the opinion of the Council, there is an increasing interest being manifested by every constituent unit. This may be construed as indicative of approval of our Association's program and policies. Generous credit is given to President Peers, President-elect Pallette, and the secretary for their time and labor in visiting every county society in presenting our policies and activities to these units, many of which had never been visited by a general officer of the Association. There is much evidence that members perceive in greater degree the value of membership, and what can be obtained by unity of purpose and action.

5. *Appeals.* The decision of one component county society and the Council was reversed by the Judicial Council, the American Medical Association, largely because of differences in procedure contained in the Constitution

and By-laws of the component county society and the California Medical Association. The decision of the Judicial Council was published in CALIFORNIA AND WESTERN MEDICINE. The Council has received and heard appeals of certain members of two other component county societies from action by these societies, involving the membership of fourteen members. The Council wishes again to emphasize the necessity of prescribed procedures when disciplinary action is taken by a county society, and stresses the advisability of consultation with a district councilor and the secretary of the California Medical Association by the officers of the county medical society faced with disciplinary action.

6. *Malpractice Insurance.*—The Standing Committee on Medical Defense has spent a great amount of time and effort in the study of the conditions existing in the field of malpractice insurance in California, and will render a report to this House of Delegates tonight. The experience of many members has been such as to compel the Standing Committee and the Council to consider the formation of our own insurance carrier, and much thought and study have been given to this matter to be ready, if the situation becomes intolerable, to set up our own malpractice insurance company. The California Medical Association has had previous experience in this field, because from 1909 to 1923 medical legal defense was offered as a part of the benefits of membership in the Association. When this service was discontinued in 1923, a number of members, realizing the value of the experience gained in these years by the legal staff throughout the state that did this work, organized a small association known as the Medical Society of the State of California, which provided its members with legal defense in any malpractice claim or suit. This society has been and is functioning steadily and quite satisfactorily to its members who have needed its service. The legal service that it gives represents only the physician involved and does not divide its allegiance between the physician and his insurance carrier, whose interests are frequently not identical. A very close coöperation exists today between this society and the malpractice insurance carriers. Its greatest total membership was about 900 and this, because of apathy, the depression, and the failure of many men to appreciate the value of legal counsel serving only their interests in malpractice suits, was reduced to 404 by January 1, 1936. For the information of the members of this House, the officers and members of the Medical Society of the State of California are and must be selected from the membership of the California Medical Association, although the society is not a part of the Association. Membership in it now costs $10 a year, and is contingent upon membership in the California Medical Association and the possession of a valid policy for not less than $5,000 in an approved malpractice insurance carrier. A brief statement of its activities during its existence follows: From 1923 to 1935, forty-nine claims arising against members were disposed of, and 119 suits brought against members were disposed of, with only one case lost. The others were either dismissed, won or settled with the consent of the physician and the insurance carrier involved. On January 1, 1936, there were still twenty cases and claims pending before the Society. Following the report of this Standing Committee on Medical Defense, the House may give expression to its wishes in the matter, and the Council recommends that the House give authorization to the Council to take positive action when, in the Council's opinion, the situation demands it.

7. *Annual Sessions.* The increasing attendance at our annual sessions, which is most gratifying, presents an important problem to the Council in selecting places with ample hotel and auditorium facilities. This fact is perceptible at this meeting. It is an obligation of the Association to complete arrangements so that it is possible for every member who desires to attend to have suitable hotel accommodations, and that auditoriums are of such size as will permit his attendance at section and general meetings. The Council, following a communication from the Committee on Scientific Work, appointed a special committee, consisting of Doctors Morton R. Gibbons, Lowell S. Goin, Lemuel P. Adams, John C. Ruddock, and Fred Gundrum, to survey our scientific sections, their status and possible amalgamation. The report of this committee is presented as Appendix B. Following is the report of the Committee on Scientific Sections, the executive group. This committee was appointed in accordance with the request of the Committee on Scientific Work and section officers, to devise a plan or plans for submission to this House of Delegates, by which the multiplicity of scientific sections of meetings at the annual convention would be limited, and at the same time more members would be enabled to hear more papers and the general practitioner would have the opportunity to follow a more diversified program than at present. A plan was presented to the Council at its meeting on May 24, and it was realized that no plan could be adopted by the House of Delegates with the hope of general approval unless the sections themselves had been consulted, and had had opportunity to study the problem. Accordingly, your committee asks for time to make adequate canvass of the sections, and suggests that the Council be authorized to make the necessary changes in system when, and if, a satisfactory plan is devised. Members of various sections are requested to give this matter their consideration, and to make recommendations to the Council of plans they think best.

8. *Amendments.*—In order that your Council may properly advance the expanding functions of the Association and insure efficiency, the Council recommends the adoption of the following amendment to the By-laws:

Resolved, That Section 20 (a) of Chapter V of the By-laws of this Association be, and it is hereby amended by adding after the phrase, 'the Committee on Industrial Practice and the Cancer Commission," and before the phrase, "and the president," contained in the first paragraph of said section, the following: "the Committee on Postgraduate Activities."

That is, to make the chairman of the Committee on Postgraduate Activities a member of the Committee on Public Relations.

In order that the experience gained by the retiring president during his two years of service as president-elect and president may be utilized to the fullest extent by the Council and the incoming officers, President Peers has recommended, and the Council heartily concurs, that the following amendments to the Constitution be adopted so that the retiring president shall serve upon the Council for one year. President Peers requests the Council to state that because this cannot be acted upon for one year, being a constitutional amendment, he makes this recommendation gracefully and guiltlessly. The amendments proposed are:

Resolved, That Section 1 of Article VII of the Constitution of this Association be, and it is hereby amended by inserting in the first paragraph thereof, after the words, "the President," the following: "the Past President"; and, be it further

Resolved, That Section 1 of Article X of the Constitution of this Association be, and it is hereby amended by inserting after the words, "a president," the following: "a past president"; and, be it further

Resolved, That Section 2 of said Article X of the Constitution of this Association, and the title thereto, be amended to read as follows: "Section 2. President-elect, When and How elected—Term of Office—Past President.—The House of Delegates at the regular annual session thereof shall elect the president-elect to serve until the adjournment of the final meeting of the House of Delegates at its next regular annual session. At the conclusion of the final meeting of the House of Delegates at its next regular annual session, such president-elect shall assume the office of president and serve as such for the term of one year thereafter or until his successor assumes office. At the expiration of his term of office, the president shall become the past president and serve as such for the term of one year thereafter or until his successor assumes office"; and, be it further

Resolved, That Section 4 of Article X of the Constitution of this Association be, and it is hereby amended by inserting in the first paragraph thereof after the word, "president," the following: "Past president."

I introduce these two sets of amendments for the Council. One can be acted upon Wednesday night. The one dealing with the past president has to stay on the table for a year, according to the provisions of the Constitution.

9. *County Hospitals.*—The persistent endeavors on the part of certain individuals and groups to secure authority to open county hospitals to all citizens regardless of their financial independence, constitute a grave situation and

problem. A special committee created at Yosemite by the House of Delegates, consisting of Doctors A. E. Anderson, Louis Packard and Earl Moody, will render a report upon this subject, based upon an enormous amount of work and devoted study by the committee. The Council recommends careful perusal of this report by every member. The Council further recommends that this matter be given preference and first consideration by this House and the Council, and that the committee be continued to work through the Council and the Committee on Public Policy and Legislation. The Supreme Court refused to grant a hearing on the decision of the Apellate Court upholding the Kern County decision closing county hospitals to nonindigent patients and thereby made this the existing law in California. Supervisors in many counties, the grange and other farm organizations, and some labor organizations, are circulating an initiative petition now that will in all probability be on the ballot in November of this year. The Council believes that this initiative contains the seeds of the most dangerous and fundamental changes in the practice of medicine ever presented to it, and urges that every facility be granted to oppose this initiative, and that every effort be put forth by physicians of California to prevent this proposed ruin of medical practice.

10. *Hospital Insurance.*—During the year, and following the passage of Assembly Bill 246 by the 1935 Legislature, there have been many discussions of the type of hospital service to be rendered by corporations formed under the provisions of this act. Consultations and meetings between the Committee on Public Relations and interested groups were held, and at the request of the Council, the Committee on Public Relations formulated standards for proposed plans necessary for their approval by the California Medical Association, referring always to the resolutions passed by the House of Delegates at its 1935 annual session, and dealing with proposed division of medical practice in the technical and professional fields. The Council, by resolution, requested the delegates to the American Medical Association to introduce the following resolution into the House of Delegates of that Association:

> WHEREAS, Certain organized lay groups in this country are endeavoring to arrange for the provision of diagnostic medical services along with, and as a part of hospital services; and
>
> WHEREAS, The provision of such diagnostic medical services will inevitably foster fundamental changes in the practice of medicine; and
>
> WHEREAS, Such changes in the practice of medicine may well result in deterioration of our present medical standards, and especially in deterioration of the quality of medical care furnished to hospital patients; now, therefore be it
>
> *Resolved,* That it is the official policy of the House of Delegates of the American Medical Association that it disapprove of the division of any branch of medicine of the technical and professional portions; and be it further
>
> *Resolved*, That copies of this resolution shall be brought to the attention of the American Hospital Association and its affiliated groups, to the end that existing arrangements permitting division in medical practice be terminated as soon as possible.

This resolution was introduced and the House of Delegates of the American Medical Association passed a resolution requiring all medical practice to be at all times under the immediate supervision of a doctor of medicine.

The Council recommends that this House reaffirm this policy which it expressed by resolution at Yosemite.

The Inter-coast Hospitalization Insurance Association was formed during the year from the Superior California Hospital Association, and is expanding rapidly. Satisfactory arrangements regarding the inclusion of case indemnities for roentgenological, clinical pathological services in the policies are apparently imminent.

The Alameda County Medical Association has been very active, and has raised, in conjunction with the associated hospitals, the necessary funds to form a corporation of a mutual type, which it was considering in 1934 and which served as a basis for the Council's recommendation at Riverside in that year, for a state-wide hospital insurance plan. The Council hopes that every assistance will be given this plan and its operation, and stresses the importance of the consideration by other county societies of a similar plan. The stabilization and control of these plans by the medical profession will do much to protect the future of medicine and will prove to the public that medicine is alive to the needs of the sick and not a blind adherent to old economic forms in a rapidly changing world.

Hall of Medical Science, San Diego Fair.—At the Pacific International Exposition there is a Hall of Medical Science, sponsored by the California Medical Association and the San Diego County Medical Society, which is admittedly one of the two best buildings at the Exposition. The quality of this exhibit and its development are due in great part to the efforts of the committee of the San Diego County Medical Society, consisting of Doctors Lyell C. Kinney, W. H. Geistweit and Maynard C. Hardy, aided by the Advisory Committee of this Association, consisting of Doctors Clarence G. Toland, E. M. Pallette, John C. Ruddock, William Roblee, C. O. Tanner, Robert Peers, Frederick C. Warnshuis, and Fred B. Clarke. These members deserve the highest praise, and their success has placed in the hands of the California Medical Association medical exhibits for the fair to be held in San Francisco in 1939.

As your interim governing body, the Council has sought to conform with the implied and recorded desires of this House. Opinions have been obtained from the membership by poll when considered advisable, and a studied effort has been made at all times to secure the greatest good for the entire Association. The Council extends its thanks to all members of the Association who have given so unselfishly of their time and effort. The election in the Fall, if the county hospital initiative is on the ballot, and the Legislature of 1937, to say nothing of changes and economic uncertainties in the practice of medicine, demand the earnest study of all physicians. The Council urges that every member of the California Medical Association use every means to familiarize himself with our problems and, when decisions have been made and policies fixed, to work shoulder to shoulder with his fellows as physicians and citizens, to the end that the fine things of medicine shall be preserved to us and to our successors.

Respectfully submitted,

THE COUNCIL.

By T. Henshaw Kelly, *Chairman.*

(Applause.)

THE SPEAKER: Thank you, Doctor Kelly. This report of the Council will be referred to Reference Committee No. 1. The next item on the docket is the report of the Trustees. Doctor Kelly again, chairman of the Board.

Report of the Trustees Of The California Medical Association

DOCTOR KELLY: This report is very short and sweet. It consists of the auditor's report of the Trustees, which is the holding company, as of December 15, 1935.

(The balance sheet was read by Doctor Kelly, who stated it was subject to the attendant comments, and should be read in connection therewith.)

INCOME AND EXPENSE ACCOUNT

INCOME:	
Interest on bonds	$1,426.34
Interest on savings accounts	543.77
Gain on the surrender of government bonds	83.12
Total income for year	$2,053.23
EXPENSE:	
Professional services	$ 125.00
Miscellaneous	22.07
Total expense for year	$ 147.07
Net profit for year	$1,906.00

On December 15, 1935, we held $25,000 in par value 4 per cent U. S. Treasury bonds, and $14,000 of 3¼ per cent Treasury bonds, making a total par value of $39,000. The indicated market value on that date was $42,179.47.

Respectfully submitted,

T. HENSHAW KELLY.

Reports of Officers and Committees

THE SPEAKER: The reports of the officers and standing committees and some of the special committees have been published in the Pre-Convention Bulletin. If there are no objections, these committee reports will be referred to the following reference committee. The report of the President, the President-Elect, the Speaker, the Secretary, the Treasurer, the Editor, the Legal Department, the Councilors, the Standing Committees, the Auditing Committee, the Cancer Commission, the Committee of Five, the Qualifying Certificate Law Committee, the San Diego Exposition Committee, the Committee on Scientific Exhibits, the Committee on Scientific Sections, the Committee on Health Insurance, that is the Committee of Six, the Committee on Tax-Supported Hospitals. These will all be referred to Reference Committee No. 1.

Doctor Kelly: If I may, I have a minority letter from one of the members of the Committee of Six which I think should be read. It was turned in too late to be included in the printed report of the committee. The minority report is by Dr. W. B. Coffey.

The Speaker: All right, Doctor Kelly. What is the supplementary report?

Doctor Kelly: Mr. Speaker, and Members of the House of Delegates: The tentative report of the Committee of Six, which, as you know, was a committee created by the House at its special meeting, to deal with the matter of health insurance in the 1935 Legislature, was sent out to the members of the committee with the request to read it and send in any questions they might have in order to correct the report before it was finally published. Through a series of circumstances, Doctor Coffey's letter dealing wtih his feelings in the matter of the report did not come in, and I think it is due him that we read the letter which he sent in as a supplement to the committee report. It reads: "To the chairman of the Committee of Six on Health Insurance: The tentative draft of your report to the President and House of Delegates of the Committee of Six on Health Insurance should, I believe, contain more facts. I do not believe that it is fair to place the blame on the California Legislature for what happened at Sacramento during and after the introduction and discussion of health insurance measures. Senator Edward H. Tickle, Leonard J. Difani, and the Coördinator-Secretary, Dr. S. J. Sullivan, are entitled to our full appreciation for their complete and unselfish coöperation. We cannot overlook the significant fact that the Senate passed a resolution signed by thirty-eight of the forty members of the Senate, the first paragraph of which reads: 'Whereas, the development of more adequate health services at rates within reasonable reach of self-supporting individuals and families of small and moderate incomes, is essential to promote the comfort, health, safety, economic security, and general welfare of the people of the State of California.'

"The Senate resolution has added meaning when we know it was passed after Senate Bill 454 was mangled and strangled by members of the medical profession, aided and abetted by dentists, hospital associations and members of organizations supported by doctors. In the face of facts which are on survey in the Senate survey and the SERA survey, we would not only sully ourselves, but be guilty of dereliction of duty if we deserted the field and left a large number of people of California who are receiving inadequate care and the many who are given no medical care or hospital care at all, to shift for themselves.

"I wish to reëmphasize what I said at the public hearing of the Senate Committee and at various meetings of the Committee of Six and other medical meetings. Until some sound method of distributing the cost of medical and hospital care is adopted and put into practice, (but not state medicine, to which I am strongly opposed), it is our duty as physicians to keep on working, no matter how much opposition we encounter from high or low places. Years ago, when workmen's compensation insurance was first discussed, members of our profession in California and elsewhere were more divided than they are today on health insurance. They adopted the unfortunate policy then which they seem to be ready to repeat today. I pleaded with the representatives of my profession twenty-five years ago to keep in touch with, and interest themselves in formulating, presenting and discussing workmen's compensation laws to guard the welfare of the injured workers, and also not to trespass on the rights and duties of attending physicians. The profession refused to heed my advice. Those that were in official positions then thought they knew better. They were opposed to workmen's compensation insurance, and they thought they could frustrate and defeat those who were for it by passing resolutions. As a result of such a futile policy, employees, employers and physicians, as well as the general public, are still suffering from mistakes made that physicians should and could have prevented. I believe we should give the Senate Committee, who are able and coöperative friends, with Senator Edward H. Tickle as chairman, our fullest coöperation in developing a more adequate health service within reasonable reach of self-supporting individuals and families of small and moderate means. While bickering and disagreement continue in the ranks of our profession, medical service paid for by taxation, federal, state and county, continues to increase. It will not be long, due to this short-sighted policy, until the general public will no longer be interested in the distribution of medical cost and the application of the insurance principle, for the simple reason that all citizens can receive medical care from these agencies, to the complete ruination of our profession and the permanent injury of public health." I wish to submit this letter as a part of the report.

Report of the Committee on Disciplinary Procedure

The Speaker: This minority report will also be referred to Reference Committee No. 1. The report of the Committee on Disciplinary Procedures consists of a by-law only and will lie on the table until Wednesday night's session, when it will be taken up for action. It is quite obvious from what Doctor Kelly has just read that it is very necessary that every delegate study the reports in this Pre-Convention Bulletin carefully. The Speaker would urge that upon you in order that we may come to the Wednesday night session, which is the all-important one, fully informed and ready to take such action as is proper and right. There is one other committee to report, Doctor Reinle's Committee on Medical Defense. Doctor Reinle. (Applause.)

Malpractice Insurance

Doctor Reinle: Mr. Speaker: The committee was assigned the task of investigating the medical defense insurance condition within this state, to determine its relation with the profession, and to suggest remedial policies if any should exist. We made a poll of the state societies and received some nine answers, and found conditions pretty much the same as in California, except in New York, where they issue a group insurance to part of their membership. The contacts were made by questionnaires sent to the entire membership, with representation of several prospective underwriters. That is, the membership of the California Medical Association received questionnaires, and we had answers from 2,700. Also, with the Legal Department of this Association and with the officers of this Association to procure, the procedure was as follows: First, the group plan. Prospective underwriters as brokers, stock company, mutual association, and reciprocal insurance, were given consideration. Second, is there at the present time an available medical defense and indemnity insurance to all members of this Association at a reasonable rate? Third, does necessity warrant the California Medical Association's taking an incursion into the insurance field? Fourth, the important factor: Can the Medical Society of the State of California pay under present circumstances?

In the consideration of the group plan, the history is important. You will recall that similar efforts were made in the past, which resulted not in the improvement of the professional security of our members but merely in dissipating the funds which were contributed. The group plan is, and will ever be, a misnomer. The individual member simply has to refuse payment of his annual payment and the group begins to break. The carrier company may and can terminate one and all policies by notifying each and all members thirty days before the anniversary date, or before the premium is due. The proscribing of such insurance is without cost to the carrier company and can be maintained one, two or three years, or when legal procedure costs and judgments exceed the premium incomes. Then the premiums are increased or the plan is terminated by the carrier. This plan has interfered with legitimate insurance, and in every location has increased premium rates in all companies. It may, however, be a solution of advantage in specialized groups, where premium rates are necessarily higher on account of potential hazards, or in small groups that can better control its policy. The underwriters fail to show anything other than their own interest. They suggest that the Association buy something unsought and unseen. They would allow this Association all the financial responsibility. Our Legal Department discussed the lawful set-up of an anticipated desire of the Association instituting an insurance program in such forms as a stock company, a mutual association, or reciprocal plan. Our counsel stressed the importance of the necessity of impounding all shares of stock in order to maintain its control to the point where no stock transfer could be made without the sanction of the Board of Directors or Trustees. A definite purpose in that was, in case the stock should fall into an estate where it could be purchased by outsiders, that his advice was that this stock should all be in escrow.

A mutual would be one in which the attorney-in-fact would have absolute control of the company, and a reciprocal would be one in which the members would elect their Board of Directors.

The counsel emphasized issuing the indemnity policies in the low brackets of $2,500 to $7,500 limit to each member, and a carrying charge equal to the now lowest commercial carrier. With reinsurance for any larger amount desired, he advised that the scope of insurance should spread to other fields of lesser hazards and be made to equalize the anticipated losses from the medical defense insurance; that is, that we would probably sell burglary and other liability insurance.

With reference to the question of available insurance to the members of this Association, many members throughout the state have been confused. The fact confronts us that, while there are at least seventy-nine companies that could write this type of insurance, only four companies continue in this special field. However, the fact remains that there are four companies doing this business in California and it is possible for members in good standing and under the age of 65 to procure a defense and indemnity policy in the following brackets: $2,500 to $7,500 for $22; $5,000 to $15,000 for $27, and $10,000 to $30,000 for $37. Provided your insurance is kept in force, there will be no discontinuance on the part of the company carrier.

The above statements seem to answer the question: "Why and where is the necessity for the California Medical Association's entering the insurance field?" Reasonable insurance is available. There is no attendant responsibility upon the officers and members of this Association, and let us remember first, last and all the time that our Association is not a plaything for any individual or group, but is essential to you, to me and to every one of us whose hopes are to practice medicine peacefully, profitably and happily.

The officers of the Medical Society of the State of California will make a definite report to the House of Delegates and, possibly, methods will be instituted to bring it to the attention of the membership of our Association. Certainly there are many who are not aware of its virtues, as Doctor Kelly explained tonight, and the importance of insurance in it. It is where we are represented by our general counsel as its attorney, who cares for our interests. It is well-officered and has a splendid legal department and offers, in addition, a brotherly service. It could be quickly evolved to meet any necessity, and I would like to state, at this time, that in this poll of the other state societies we find that the services rendered by the Medical Society of the State of California to us are at less cost than those rendered by any other society except one. The others charge considerably more, up to $24 per annum for the same service, or probably not as good, as is given us. Now in view of the fact that this committee can at the present time sense no necessity of the Association's entering the insurance business, and since we find reasonable insurance available to the membership at present, we respectfully recommend to the House of Delegates that the subject of medical defense be deferred until such time as some warranted action becomes necessary; so that at any time when we cannot buy reasonable, adequate and satisfactory insurance, then, and then only, should this Association enter the insurance business. I thank you. (Applause.)

The Speaker: This brief report in no wise gives you an adequate idea of the amount of work the committee has put in on this subject. They worked steadily and continuously, and their conclusions were not reached without very adequate consideration. This report will be referred to Reference Committee No. 1.

Report of the A. M. A. Delegates on the Kansas City Session

The chair will recognize Doctor Best, who will give us a report from the delegates to the American Medical Association convention held in Kansas City. Doctor Best.

Doctor Best: Mr. Speaker, Officers, and Members of the House of Delegates: Your delegates at the 1936 American Medical Association House of Delegates meeting in Kansas City consisted of Doctors Pallette, Dukes, Molony, Shepard, Scott, Kinney and Best. The delegates offer the following sketchy report of the proceedings at the House of Delegates. Doctor Pallette was elected chairman of the California delegates. Out of the seven California delegates, we were fortunate to have three appointed on important reference committees. Doctor Dukes was appointed on the Reference Committee on Medical Education and Hospitals; Doctor Scott was appointed on the Reference Committee for Miscellaneous Business, and your speaker was appointed on the Reference Committee for Rules and Order of Business. Valuable assistance was rendered this year to the California delegates by the efforts of our secretary, Doctor Warnshuis, who was very active in contacting the various members of the House. I may state, as a passing note from President McLester's address, the following is of interest, I think, to all of us: "It is becoming more apparent that doctors must become more and more public activity conscious."

Resolutions regarding a division of technical and professional services were presented by the Pennsylvania delegation and by the California delegation for the x-ray section. These were referred to the Committee on Medical Education and Hospitals, and at the final session the House of Delegates voted that technical service was a form of medical service, and therefore not separate from medical services. This applies to x-ray and other services, such as pathology.

Resolutions were introduced regarding the qualification of medical students, regarding the accrediting of hospitals for internship, and the status of students educated in foreign medical schools. Doctor Molony was instrumental in one of these resolutions.

As a matter of interest to some of us in California, it was the discussion of some of the New York delegation regarding the form of medical bar. A report was handed to each delegate, coming from the Legal Department, Doctor Woodward, revealing many arguments against such a set-up.

As you probably all know, after a great deal of discussion, which was deleted from the minutes, it was moved by the House of Delegates that Dr. Tate Mason be installed as president of the American Medical Association *in absentia*. This motion was made by our president-elect, Doctor Pallette, and seconded by Doctor Molony.

Regarding hospitals, the Committee on Medical Education and Hospitals considered it wise to insist on hospital staffs being members of the county society in order to qualify for intern training. It was also advised that medical schools devote a definite time to the teaching of medical economics.

Of interest to us out West, a resolution was presented by Oregon regarding hospitals receiving patients from certain hospital staff doctors whose patients were obtained in questionable or unethical manner, such hospitals to be refused the right of the Class A rating, fifth year intern training.

Another point of interest was a report by Doctor Carey which stated that consultation with the Federation of Labor brought forth the fact that labor does not want state medicine, and wishes to take care of its own medical problems.

An amendment to the by-laws of the American Medical Association was offered, giving the Judicial Council the power to try members of the American Medical Association direct.

Relating to the rating of hospitals in case of question regarding a hospital getting the proper rating, the complaint is to go to the state medical organization in which that hospital is located.

It was resolved that doctors whose diplomas were granted in foreign lands must obtain a license to practice in the country of their education first, and then either serve a year of internship in a Class A hospital in this country or complete a fourth year in a Class A medical school. This is the resolution that was introduced by Doctor Molony. I thank you. (Applause.)

The Speaker: Thank you, Doctor Best.

Legal Counsel's Report

Our legal counsel has a supplementary report, and at its conclusion the speaker will ask him to introduce to you an invited guest. The councilors this morning asked Mr. Alfred Siemon, of Bakersfield, who has been in the thick of the fight in county hospital work there, and was our friend through all this time, and a friend of the taxpayers who sees things straight. He knows more about this subject, probably, than any man in California, and we have asked him to come and talk to us tonight about it. Mr. Hartley Peart, our attorney. (Applause.)

Mr. Peart: Mr. Speaker, President Peers, and Members of the House of Delegates: I will make this report very brief, as I have already printed the report of the department for the year. One or two matters have come up since the report was printed.

Anesthesia Case.—The first matter is the case brought by Doctor Chalmers-Francis and others of Los Angeles against a hospital there and a nurse. Mr. Leroy Anderson, of Los Angeles, tried the case, and at the conclusion of the trial, which resulted unfortunately, the Council instructed us to assist on the appeal. Some of it was contained in our report, but since the report was published the Supreme Court, I regret to say, has decided the case against us. I would like to quote just a little bit from the opinion. We labored very hard on the briefs in this case, and were very happy to have the approval of Doctor Botsford and other anesthetists of San Francisco, and Doctor Francis and his counsel at Los Angeles, the counsel, of course, participating with us in the briefs. We thought that they were unanswerable, but the Supreme Court thought otherwise, and I want to call attention to what I think is the nub of this decision. They say:

> "There was much testimony as to the recognized practice of permitting nurses to administer anesthetics and hypodermics. One of the plaintiff's witnesses testified to what seems to be the established and uniformly accepted practice and procedure followed by surgeons and nurses, and that is, that it is not diagnosing nor prescribing by the nurses within the meaning of the Medical Practice Act. We are led further to accept this practice and procedure as established when we consider the evidence of the many surgeons who supported the contention of the defendant nurse and whose qualifications to testify concerning the practice of medicine in this community and elsewhere were established beyond dispute."

The Council has not yet determined whether we are to proceed further in the matter. We were anxious to have the court rule on the question squarely as to whether or not a physician, as the plaintiff in this case, was entitled to an injunction to prevent a non-licensed person from practicing. The court, however, says that it is not necessary to the decision in this case to decide that particular point.

We were also anxious to have other matters, particularly the matter of the delegation, if the court so rules and it is to be so understood in this decision, as to whether or not the delegation of a professional service can be made to a nurse or to any person other than a nurse, or at all.

Pacific Employers' Insurance Company.—Another case decided during the year in which we were more fortunate, and which is contained in the report, is the case of the Pacific Employers' Insurance Company. For the first time in California, we have established that a corporation cannot practice medicine directly or indirectly. In justice to that company (and this is not set forth in the report, but perhaps should have been), I would like to state that, following that decision the company modified and changed all the policies in conformity with the decision.

It has been a very extraordinary year, and probably it is fitting that during the year a fundamental rule in malpractice has been changed in this state. We have always assumed that the statute of limitations commenced to run from the date of the negligent act or omission. In the case of *Keiswell* v. *Hirsh*, a case arising in Los Angeles and handled by Mr. Gilbert's office for the Medical Protective Company of Fort Wayne, the Supreme Court says that, where a tube is allowed to remain in the abdomen of the patient, according to testimony, the negligence is continuing and is a repeated act of negligence for every day that the tube is allowed to remain there, and that the cause of action does not commence to run, so far as the statute is concerned, until the tube is removed. That is a very significant case for the members of the profession.

Another case of importance is the one that has been referred to tonight, *Goodall* v. *Bright*, where we were successful in establishing that the county hospitals are to be limited to the use of indigents. The case has excited a great deal of attention throughout the state with some very amazing results, namely, in San Joaquin County, at least according to the newspapers, the Board of Supervisors said they would not recognize the decision. I do not know whether they are proceeding according to that statement or not.

The Council requested me to telephone to Mr. Siemon today to ask him to come here, and he has flown from Bakersfield to give you first-hand information on conditions in Kern County. Mr. Siemon commenced this work for the Association a couple of years ago, and represented the plaintiff doctors and taxpayers in that action throughout the litigation. It was very strenuous litigation. He had to fight all the way, and it has been a great source of satisfaction to me to have commended him to the doctors for selection as their representative there. He is able, courageous, efficient, and a friend of the medical profession. I take great pleasure in presenting him to you. (Applause.)

Mr. Alfred Siemon of Bakersfield was presented. His remarks will appear in a subsequent issue.

The Speaker: Are there other supplementary reports of committees or officers? If not, the next order of business is the introduction of Resolutions.

Submittal of Resolutions by Delegates

The chair recognizes Doctor Barrow of Los Angeles.

Doctor Barrow: This resolution is presented to the House of Delegates for its consideration on Wednesday evening:

Resolution No. 1: On Hospital Insurance; Exclusion of Medical Services*.

The Speaker: This resolution will be referred to Reference Committee No. 2.

The chair recognizes Doctor Anderson of Fresno.

Dr. Anderson: Mr. Speaker and Members of the House of Delegates: Your Committee on Tax-Supported Hospitals wishes to submit the following recommendations:

Resolution No. 2: Concerning County Hospitals.

The Speaker: This resolution is referred to Reference Committee No. 2.

The chair recognizes Doctor Canelo of San Jose.

Doctor Canelo: The Santa Clara County Medical Society has unanimously requested that the delegates from that district present the following resolution:

Resolution No. 3: Regarding Payment for Hospital and Medical Services When Rendered in Automobile Accidents.

The Speaker: This resolution is referred to Reference Committee No. 2.

The chair recognizes Doctor Goin of Los Angeles.

Doctor Goin: I wish to submit the following resolution:

Resolution No. 4: On Procedure in Presenting Proposed Laws to the Legislature.

---

* This and other resolutions are not printed here, because they are given as presented, and as amended, in the report of Reference Committee No. 2, which follows on page 86.

The Speaker: This resolution is referred to Reference Committee No. 2.

The chair recognizes Doctor Chalmers-Francis of Los Angeles.

Doctor Chalmers-Francis: The Anesthesiology Section of the California Medical Association respectfully submits to the House of Delegates the following:

Resolution No. 5: On the Practice of Anesthesia as a Medical Service.

The Speaker: This resolution is referred to Reference Committee No. 2.

The chair recognizes Doctor Chandler of San Francisco.

Doctor Chandler: The Board of Directors of the San Francisco County Medical Society has instructed its delegation to introduce the two following resolutions:

Resolution No. 6: On Malignancy in Relation to industrial Insurance.

Resolution No. 7: On Practice of Medicine by Corporations.

The Speaker: These two resolutions are referred to Reference Committee No. 2.

The chair recognizes Doctor Stone of San Francisco.

Doctor Stone: I wish to introduce the following resolution to the House of Delegates:

Resolution No. 8: Regarding Practice of Medicine by Corporations.

The Speaker: This resolution is referred to Reference Committee No. 2. If there are no other resolutions, is there any other business to come before the House before it adjourns?

The Secretary: Mr. Speaker, it is suggested, in view of the fact that the minutes of this meeting are being recorded, that these minutes be edited by the Speaker of the House of Delegates, the Chairman of the Council, and the Secretary, and thus constitute the minutes for this session.

The Speaker: If there is no objection, that ruling will be made.

(Announcements were made of the times and places for the meetings of the two Reference Committees.)

The meeting was adjourned at 11:00 p. m.

* * *

SECOND MEETING

Wednesday Evening, May 27, 1936

The second meeting of the House of Delegates of the California Medical Association was convened in the ballroom of the Hotel del Coronado, Coronado, California, on Wednesday, May 27, 1936, at 7:30 p. m., with the speaker, Dr. W. W. Roblee of Riverside presiding.

The speaker instructed the secretary to call the roll.

The Secretary: Mr. Speaker and Members of the House of Delegates: It is my unpleasant duty to advise the Speaker of the House that our esteemed president, Doctor Peers, was called to San Francisco this afternoon because of the very serious illness of his mother. With the consent of the House, I should like to recommend that we mark him present at this meeting.

The Speaker: It is so ordered.

The secretary then called the roll.

The Speaker: The roll call is complete. There is a provision in the By-laws whereby if there be neither delegate nor alternate present, any other member of that county society who may be present can be seated. Are there any others who can be seated under that rule? If so, announce them now. The call is complete. The House is open and deemed ready for business.

I have a very pleasant announcement to make to you, one that you all have been anticipating. The next annual session of this convention will be held at Del Monte.

The Speaker: Permit me to remind every delegate who addresses the House to announce his name and his county.

The next item of business on the docket is always a very interesting one. We have come to the election of officers for the ensuing year. The Speaker will entertain nominations for president-elect.

Election of President-Elect

Doctor Geiger: Mr. Speaker, J. C. Geiger of San Francisco.

The Speaker: Doctor Geiger of San Francisco.

Dr. Geiger: Mr. Speaker, Members of the House of Delegates: It is my honor, and the honor of San Francisco County, to nominate a colleague of standing in our community, a friend and a man that we are glad to honor tonight. It is my pleasure to nominate for president-elect Dr. Howard Morrow of San Francisco. (Applause.)

The Speaker: Is there a second to Doctor Morrow's nomination?

Doctor Shoemaker: Mr. Speaker, Doctor Shoemaker of Los Angeles.

The Speaker: Doctor Shoemaker.

Doctor Shoemaker: It gives me great pleasure to second the nomination of Dr. Howard Morrow. I feel that the unanimous support of this House of Delegates is due Doctor Morrow for his outstanding support of scientific medicine and for his knowledge of the medical problems of the whole State of California.

Doctor Goin: Mr. Speaker, Doctor Goin of Los Angeles.

The Speaker: Doctor Goin.

Doctor Goin: Mr. Speaker, and members of the House: From time to time, but all too infrequently, there arises an opportunity to show honor to some man who has particularly distinguished himself in the field of medicine. In nominating Dr. Howard Morrow as president-elect of this Association, we are offering to a man who has long, faithfully, quietly and efficiently worked for organized medicine, and for the benefit of the California Medical Association, and in offering him this dignity we are conferring honor both upon ourselves and upon Doctor Morrow. I take pleasure in seconding Doctor Morrow's nomination.

The Speaker: Are there any other seconds? Are there any other nominations? If not, the Speaker declares the nominations closed. How will you elect?

Doctor Reinle: Mr. Speaker, Doctor Reinle of Oakland.

The Speaker: Doctor Reinle.

Doctor Reinle: I move that the secretary cast the ballot.

The Speaker: You have heard the motion that the secretary cast the ballot for Doctor Morrow as president-elect for the coming year. All those in favor say, aye. Contrary, no. The ayes have it. It is so ordered.

The Secretary: Mr. Speaker, your secretary does so cast.

The Speaker: Doctor Morrow is elected. (Applause.) I appoint Dr. J. C. Geiger of San Francisco and Dr. George Kress of Los Angeles to bring Doctor Morrow to the platform. (Applause.)

(Doctor Morrow is escorted to the platform.)

Members of the House of Delegates: I present to you the president-elect of the California Medical Association. Dr. Howard Morrow of San Francisco.

Doctor Morrow: Mr. Speaker, Members of the House of Delegates of the California Medical Association, Ladies, and Gentlemen: I greatly appreciate the honor which you have conferred upon me, and also of the privilege of being able to follow in the footsteps of President Pallette. I assure you that during my term of office I will always work hard for organized medicine. (Applause.)

Officers of the House of Delegates

The Speaker: I turn the gavel over to the Vice-Speaker of the House, Doctor Graves.

The Vice-Speaker: Nominations are in order for the Speaker of the House for the ensuing year.

Doctor Dukes: Mr. Speaker, Doctor Dukes of Alameda.

The Vice-Speaker: Doctor Dukes.

Doctor Dukes: Mr. Speaker and Members of the House of Delegates: In 1895 there stood upon a platform much larger than this a class about to graduate. One of the gentlemen in that class had on a long frock coat, a white tie and a white shirt. He has become a distinguished member of the medical profession. He has been honored as your Speaker for the past year, and it is with great pleasure that I again nominate my classmate. Will Roblee of Riverside for Speaker of this House. (Applause.)

The Vice-Speaker: Is there a second to the nomination?

Doctor Kelly: Mr. Speaker, Doctor Kelly of San Francisco.

Doctor Kelly: Having listened to Doctor Duke's nomination of Doctor Roblee, not having known Doctor Roblee until he forgot the white shirt but wore white whiskers, and having watched him preside Monday night and his performance tonight, I do not know of any better thing I can do than second Doctor Duke's nomination of him for Speaker of our House of Delegates for the succeeding year. (Applause.)

It was moved and seconded that the nominations be closed and the ballot cast. The secretary cast the ballot.

The Vice-Speaker: Doctor Roblee is declared the Speaker for the ensuing year. (Applause.)

Doctor Roblee: Thank you, gentlemen. This is a business job you have handed me. There is a lot of business to do and we will proceed immediately to it. (Applause.)

We now have the nomination for vice-speaker.

Mr. Speaker: Doctor Magan of Los Angeles.

Doctor Magan: I desire, Mr. Speaker, to nominate for the vice-speakership, Dr. John Graves of San Francisco. (Applause.)

The Speaker: Is there any second? The motion was seconded.

The Speaker: Are there any other nominations? If not, I declare the nominations closed.

It was moved and seconded that the ballot be cast. The secretary cast the ballot.

The Speaker: Doctor Graves will serve you for another year. (Applause.)

Doctor Graves: All I can say is, I thank you for the honor. (Applause.)

Election of District Councilors

The Speaker: We now proceed to the election of the councilor of the Second District. Dr. Carl R. Howson is the incumbent. Nominations are in order.

The Secretary: Mr. Speaker, the delegates of the Los Angeles County Medical Association, represented by Lowell S. Goin and Harlan Shoemaker of the Los Angeles County Medical Association, nominate Dr. Carl Howson for councilor of the Second District to succeed himself. (Applause.) The nomination was seconded:.

Doctor Snure: Mr. Speaker, Henry Snure of Los Angeles.

The Speaker: Doctor Snure.

Doctor Snure: I move the nominations be closed and that the secretary cast the ballot for Dr. Carl Howson to succeed himself. Doctor Ullmann of Santa Barbara seconded the nomination. The secretary cast the ballot.

The Speaker: Doctor Howson is elected. Stand up, Carl, and take a bow. (Applause.)

The Speaker: A candidate to succeed the incumbent, Dr. Alfred L. Phillips, from the Fifth District. Nominations are in order.

The Secretary: I have the following communication: A caucus of all seated delegates from the Fifth Councilor District was held and they have unanimously endorsed and hereby nominate C. Kelly Canelo as councilor for the Fifth Councilor District. Signed by the six delegates from that district.

The Speaker: Are there other nominations?

Doctor Scatena: Mr. Speaker, Doctor Scatena of Sacramento.

The Speaker: Doctor Scatena of Sacramento.

Doctor Scatena: I wish to place in nomination a man who has served his district for many years, and one who has served the California Medical Association with integrity and honesty, Dr. Alfred L. Phillips of Santa Cruz. (Applause.)

The Speaker: Dr. Alfred L. Phillips is placed in nomination. Are there any other nominations?

Doctor Ewer: Mr. Speaker, Doctor Ewer of Alameda County.

The Speaker: Doctor Ewer of Alameda.

Doctor Ewer: I take pleasure in seconding the nomination of Doctor Phillips, who has long occupied that position well and ably. I do this on behalf of the delegates of Alameda County. (Applause.)

The Speaker: Are there other nominations or seconds?

Doctor Larson: Mr. Speaker, Doctor Larson of Los Angeles.

Doctor Larson: I wish to endorse and second the nomination of Doctor Phillips.

Doctor Toland: Mr. Speaker, Doctor Toland of Los Angeles.

The Speaker: Doctor Toland of Los Angeles.

Doctor Toland: I rise to second the nomination of Doctor Phillips for councilor from the Fifth District.

The Speaker: Are there other nominations or seconds?

Doctor Powell: Mr. Speaker, Doctor Powell of San Joaquin. San Joaquin wishes to second the nomination of the man who has been nominated by the majority of the delegates in his own district. I want to second the nomination of Doctor Canelo for councilor.

It was moved and seconded that the nominations be closed. The Speaker named the following tellers: Doctors Best, Reinle, Powell, and Packard.

The Secretary: Mr. Speaker, as a matter of record there are 135 delegates entitled to vote.

The votes were tallied.

The Secretary: Mr. Speaker: Out of a possible 135 votes, Doctor Canelo received 30, Doctor Phillips 103. (Applause.)

The Speaker: Gentleman, by your vote you have elected Dr. Alfred C. Phillips to succeed himself as councilor of the Fifth District. Doctor Phillips, will you stand up, please, and give us a good bow? (Applause.)

The term of C. E. Schoff as councilor of the Eighth District is expired. Nominations are in order.

The Secretary: Mr. Speaker, delegates of the Eighth District, meeting in caucus, beg to submit the name of Dr. C. E. Schoff as councilor for the Eighth District for the ensuing term. Signed by Dr. F. N. Scatena of Sacramento and all the other delegates of that district. Nomination seconded.

The Speaker: Are there any other nominations or seconds? If not, the nominations are declared closed.

Doctor Reinle of Alameda moved that the secretary cast the ballot in favor of Doctor Schoff, and the motion was seconded by Dr. Carl Howson of Los Angeles. The ballot was cast.

The Speaker: The ayes have it and Doctor Schoff is declared elected. (Applause.)

Election of Councilors-at-Large

The Speaker: The term of Dr. C. O. Tanner, councilor-at-large, has expired. Nominations are in order for a successor to Doctor Tanner.

Doctor McClendon: Mr. Speaker, Doctor McClendon of San Diego.

The Speaker: Doctor McClendon of San Diego.

Doctor McClendon: I would like to place in nomination again, as I did three years ago, the name of C. O. Tanner as councilor-at-large.

Mr. Speaker: Is there a second to that nomination? Are there other nominations?

Doctor Barrow: Mr. Speaker, Doctor Barrow of San Diego.

The Speaker: Doctor Barrow of San Diego.

Doctor Barrow: As I had the pleasure three years ago to second the nomination of Doctor Tanner, in expressing my own desires and those of the San Diego delegation, I take great pleasure in now seconding the nomination of Doctor Tanner.

Mr. Speaker: Are there other seconds or other nominations? If not, the Speaker declares the nominations closed. How will you vote?

It was moved and seconded that nominations be closed.

The Speaker: The ayes have it. Doctor Tanner has been reëlected to the position. (Applause.)

The Speaker: The term of T. Henshaw Kelly as a councilor-at-large has also expired. Nominations are in order.

The Secretary: The delegates of the San Francisco Medical Society unanimously nominate Dr. T. Henshaw Kelly as councilor-at-large. Signed by Loren R. Chandler, chairman of the delegation. (Applause.)

Doctor Molony: Mr. Speaker, Doctor Molony of Los Angeles.

The Speaker: Doctor Molony of Los Angeles.

Doctor Molony: It gives me and, I am sure, also the members of the Los Angeles County and other Southern California delegations a great deal of pleasure to second the nomination of Doctor Kelly. There is no one, I am sure, in this whole House of Delegates who more richly deserves reëlection in the House of Delegates or as councilor of this Association than Doctor Kelly. It is a very happy occasion for all of us that Doctor Kelly has been nominated for this position. (Applause.)

The Speaker: Are there other nominations?

Mr. Speaker: Doctor Chandler of San Francisco.

The Speaker: Doctor Chandler.

Doctor Chandler: It gives me more than pleasure, if that is possible, to second the nomination of T. Henshaw Kelly as councilor-at-large. He gives about ten times as much of his time to this Association as any man should be asked to give, and he gives about four times as much as he himself should give. It is a great pleasure to second the nomination of Doctor Kelly.

It was moved and seconded that the nominations be closed.

The secretary cast the ballot.

The Speaker: Doctor Kelly is elected. (Applause.)

Election of Delegates to the American Medical Association

We now come to the election of delegates to the American Medical Association. The term of Dr. C. A. Dukes of Oakland has terminated. Nominations are in order.

Doctor Crosby: Mr. Speaker, Doctor Crosby of Alameda County.

The Speaker: Doctor Crosby of Alameda.

Doctor Crosby: Perhaps there is no man who has been willing to give the time, and no man who retains the quintessence of the energy of that famous class of '95 so well as the bald-headed incumbent whose term has now expired. We are amazed at the work, at the consistent energy and earnestness of Charlie Dukes in all of the things for the advancement of medicine that we are seeing, and it is a great pleasure and a privilege to nominate him to succeed himself. (Applause.)

Doctor Lawson of Alameda and Doctor Toland of Los Angeles seconded Doctor Duke's nomination.

The Speaker: Are there any other nominations? If not, we declare the nominations closed. It was moved and seconded that the secretary cast the ballot. The secretary did so cast.

The Speaker: The ayes have it. Charles Dukes, for the glory of the class of '95, will you please stand?

Clarence Toland's term has also expired. Nominations are in order for that position.

Doctor Askey: Mr. Speaker, Doctor Askey of Los Angeles.

The Speaker: Doctor Askey of Los Angeles.

Doctor Askey: I am unable tonight to do justice to the man whose name I wish to present to this body. He is a man who is known to all of you, and who is loved by all of us—a man who has done much for organized medicine in this State. I refer to our president-elect, Dr. Edward M. Pallette. (Applause.)

The Speaker: Doctor Pallette is placed in nomination. Are there other nominations or seconds?

Doctor Larson: Mr. Speaker, Doctor Larson of Los Angeles. I second the nomination of Doctor Pallette.

The Speaker: Doctor Larson of Los Angeles seconds. Are there others? Other nominations? If not, the Speaker declares the nominations closed.

Doctor Kelly of San Francisco moved and Doctor Dukes of Alameda seconded the motion, that the secretary cast the ballot. The secretary did so cast.

The Speaker: You have elected Doctor Pallette. Doctor Pallette, will you stand and take another bow?

The Speaker: The term of Junius B. Harris has expired. Nominations are in order.

Doctor Harris: Mr. Speaker, Doctor Harris of Sacramento. As an incumbent it is my privilege, and indeed it is my pleasure, to place in nomination to succeed myself one of the greatest men who has ever adorned the chair of presidency of our Association, and you all know I am nominating Dr. Bob Peers—Dr. Robert A. Peers of Colfax. When I do this, I am nominating the man who has gone the length and breadth of this State and has visited every medical society, unifying and coördinating all the different factions that we have; a man who will, at our national meeting, lend force and dignity and add to the glory of the name of California. I am enthusiastic and hopeful when I place in nomination the name of Robert A. Peers to succeed Junius Harris.

The Speaker: Dr. Robert A. Peers is nominated. Are there other nominations?

It was moved and seconded that the nominations be closed. The motion was made and seconded that the secretary cast the ballot. The secretary did so cast.

The Speaker: You have elected Dr. Robert Peers.

A successor to William R. Molony is next in line.

Doctor Adams: Mr. Speaker, Doctor Adams of Riverside.

The Speaker: Doctor Adams of Riverside.

Doctor Adams: I want to afford myself the pleasure of placing in nomination for delegate to the American Medical Association for the ensuing term the name of a man who has served the people of the State of California, as well as the medical profession of this State, on the Board of Medical Examiners during the last twenty-three years. He has served as president of that board during the last few years. He has been a faithful, courageous and dynamic force on the floor as vice-counsel in the deliberations for scientific medicine. Mr. Speaker, I afford myself the pleasure of nominating Dr. William R. Molony to succeed himself.

This nomination was seconded.

The Speaker: Are there any other nominations? If not, the Chair declares the nominations closed. Doctor Howson moved and Doctor Askey seconded, that the secretary cast the ballot. The secretary did so cast.

The Speaker: Dr. William R. Molony has been elected to succeed himself.

The Speaker suggests that, inasmuch as it is quite unnecessary to have seconds, we speed this up a bit now by cutting out the seconds.

Now an alternate for Doctor Dukes of Oakland.

Doctor Makinson: Mr. Speaker, Doctor Makinson of Alameda.

The Speaker: Doctor Makinson of Alameda.

Doctor Makinson: I wish to place in nomination a man whom you all know, who is well known throughout the state, who has served twenty-five years in the Council, a past president of the California Medical Association, none other than our good friend, Doctor Ewer, to succeed himself.

The Speaker: Are there any other nominations? Doctor Ewer is nominated. If there are no other nominations, the Speaker declares the nominations closed. Doctor Crosby of Alameda moved, and Doctor Reinle of Alameda seconded, that nominations be closed and the secretary cast the ballot. The secretary did so cast.

The Speaker: It is so ordered. Doctor Ewer is reelected. (Applause.)

An alternate in place of Dr. Edward M. Pallette.

Doctor Daniel: Mr. Speaker, Doctor Daniel of Los Angeles.

The Speaker: Doctor Daniel of Los Angeles.

Doctor Daniel: I wish to nominate a man who has been president of the California Medical Association and a man who has been on the Board of Councilors for years, Dr. William H. Kiger. (Applause.)

The Speaker: Doctor Kiger is nominated. Are there other nominations? If not, the nominations are closed. It was moved by Doctor Askey of Los Angeles, and seconded by Doctor Kelly of San Francisco, that the ballot be cast. The secretary did so cast.

The Speaker: You have elected William H. Kiger as alternate. (Applause.)

An alternate to Dr. Robert M. Peers is now to be elected.

Doctor Schoff: Mr. Speaker, Doctor Schoff of Sacramento. We are quite famous in northern California for the adornments that some of our outstanding men attain up here. I refer particularly to their red heads. You have just listened to June Harris, the outgoing representative, make his nomination of Doctor Peers, who is also a redhead, and I in turn take pleasure in nominating as the alternate to Doctor Peers, Fred F. Gundrum of Sacramento.

The Speaker: Fred F. Gundrum is nominated. Are there other nominations? If not, we declare the nominations closed. Doctor Howson moved, and Doctor Dukes seconded, that the secretary cast a unanimous ballot. The vote was taken.

The Speaker: You have elected Dr. Fred Gundrum. (Applause.)

Nomination for alternate for William R. Molony is in order.

Doctor Remmen: Mr. Speaker, Doctor Remmen of Los Angeles.

The Speaker: Doctor Remmen of Los Angeles.

Doctor Remmen: I have the honor to place in nomination the name of one of our colleagues who has served long and faithfully on behalf of the Association, Dr. John C. Ruddock.

The Speaker: John C. Ruddock is nominated. (Applause.) Are there other nominations? If not, the nominations are closed. Doctor Kelly of San Francisco moved, and Doctor Schaupp of San Francisco, seconded a motion that the secretary cast the ballot.

The Speaker: The ayes have it. It is so ordered. The secretary cast the ballot.

I now turned the gavel over to the Vice-Speaker.

Amendments to By-Laws: Disciplinary Code

Vice-Speaker: The House will have the authority to add certain amendments to the by-laws, copies of which are to be found in the Pre-Convention Bulletin, and they will be presented by the chairman, Doctor Roblee, and your action will be asked after the reading of each amendment.

Doctor Roblee: Mr. Speaker, Gentlemen of the House: In consequence of the social and economic unrest that have developed in our land, and because of the repercussions thereof which have come to the members of our profession, not only have sharp differences of opinion developed among us as to courses to be pursued, but in an increasing number of instances these have resulted in charges of unethical conduct against members of component county units. These hearings have developed the fact that there is now a total lack of uniformity in the various constitutions and by-laws dealing with this subject. It is very easy to enroll a man as a member of a county medical society, but once he is in, he has established for himself certain moral, professional and property rights that are of great value to him. He should be secure in those rights, so long as he conforms to the rules laid down by the organization, and the civil courts have confirmed this right in numerous cases on record. In our organization this right is provided for by appeals to the Council of the California Medical Association, thence to the Judicial Council of the American Medical Association; and it can be taken from thence to the civil courts.

During the past two years your Council has heard several appeals from the decisions of the county societies. One case was carried to the American Medical Association, and there the decision was reversed entirely because of mistakes made in procedure. Your Council appointed a committee to survey this entire question, and at the Monday evening session of this House it offered a by-law which, if adopted, it feels will chart the course for the county units which, if accurately followed, will protect the interests of all parties concerned. It covers every moral and legal requirement. This and other drafts of the by-law have been carefully reviewed by our attorney, the Council, and the Executive Committee, and its adoption is recommended. It will be necessary to amend the draft which you hold in your hands in a few details in view of certain experiences the Council has had in conducting some recent appeals that were before it. The adoption of this by-law will make it automatically a part of the by-laws of every component county society and the needed uniformity will be obtained. The warrant for this is found in Chapter I, Section 1 of the By-Laws of the California Medical Association. In order to effect a harmonious result, and in order that the by-laws as amended may not lack organization, the following amendments take the form of, first, an outright repeal of Sections 2 to 5, inclusive, of Chapter II of the by-laws of the California Medical Association, and, second, a substitution therefor of new sections 2 to 5, inclusive, of Chapter II, incorporating sections governing disciplinary procedure in the component county societies, as well as disciplinary procedures in the California Medical Association itself. This method makes the amendment somewhat bulky, but in the end it will avoid a great deal of the confusion that would necessarily arise if specific new sections should be added to Chapter II without regard to the resultant lack of organization. Your committee offers this by-law:

Resolved, That the by-laws of the California Medical Association be amended by striking out all of Sections 2, 3, 4, and 5 of said Chapter II thereof and by inserting in lieu of said Sections 2, 3, 4, and 5 of Chapter II, new sections to be numbered Sections 2, 3, 4, and 5, respectively, of said Chapter II and reading as follows:

"Section 2. Termination of Membership.

"(a) By Expulsion from Component County Societies.—Expulsion from any component county society, after due proceedings in accordance with these by-laws, upon becoming final terminates all the rights and privileges in this Association of the member so expelled.

"(b) By Failure to Pay Dues.—If the annual assessment of dues, payable to this Association by any member of this Association, is not paid on or before April 1 of any year, such member shall automatically lose his membership in this Association as of April 1 of such year. The Council of this Association, in his discretion, upon payment of such unpaid dues, and any other assessments or dues accruing thereafter, may at any time reinstate such member."

Mr. Speaker, I move the approval of the by-laws so far as read.

Vice-Speaker: You have heard the by-law as read by the chairman of the Disciplinary Procedures Committee. What is your pleasure? Will someone move its adoption?

Doctor Best of San Francisco moved its adoption, and Doctor Askey of Los Angeles seconded.

Vice-Speaker: It has been regularly moved and seconded that the amendment so far as read be adopted. Is there any debate? All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(c) By Revocation of Physician's and Surgeon's Certificate.—Any active member whose license to practice medicine and surgery in the State of California is revoked shall, upon receipt of sufficient written evidence of such revocation and of its legal finality by the Secretary of this Association, thereupon cease to be a member of this Association."

Mr. Speaker, I move that the word "sufficient" in the third line be stricken out, and the words in the next line, "and of its legal finality," be stricken out.

Vice-Speaker: You have heard the motion. Is there a second? Doctor Larson of Los Angeles seconded.

Vice-Speaker: Is there any debate? All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(d) Acts and Conduct Subjecting Member to Censure, Suspension or Expulsion by Component County Society.—Any active member of a component county society who has been adjudged guilty of a criminal offense involving moral turpitude, or who has been duly adjudged guilty by his society, in accordance with the procedural requirements of these by-laws, of gross misconduct as a physician or a surgeon or of a violation of any of the provisions of the constitution or by-laws or principles of professional conduct of his society or of the principles of medical ethics promulgated from time to time by this Association or by the American Medical Association, shall be subject to censure, suspension or expulsion from his society by such component county society."

I am not going to move the adoption of these until we come to some deletions or changes. I shall pause for a moment after each paragraph, and if anyone has anything to offer on the subject rise and so state.

"(e) Right of Committee on Membership and Organization of this Association to Prefer Charges.—(This is a new section.) If a member of this Association is believed by the Committee on Membership and Organization of this Association to be guilty of conduct justifying censure, suspension or expulsion from his component county society, said committee may prefer written charges in the form and in the manner hereinafter specified with the secretary of the accused member's county society and may, through a member or members thereof, perform all acts that are reasonably necessary and proper in the prosecution of said charges."

That gives the California Medical Association, through its committee, an opportunity to initiate proceedings direct in case there is a flagrant violator of medical ethics against whom, for some reason or other, the county society does not feel itself ready to initiate charges. I will say that the American Medical Association beat us to it on this provision and adopted a similar provision at the last meeting, whereby the American Medical Association can also initiate proceedings direct against a member if it is deemed necessary.

"Section 3. Procedure to Be Followed by Component County Societies with Respect to Involuntary Loss of Membership.

"(a) Disciplinary Procedure for Component County Societies.—The procedure to be followed by each component county society with respect to the censure, suspension or termination of membership of a member shall be:"

Mr. Speaker, I move that the words "termination of membership" be deleted and there be substituted therefor the word "expulsion."

Vice-Speaker: You have heard the motion. Is there a second?

Doctor Scarboro of Fresno seconded the motion.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(1) Charges.—Formal Requirements.—A Formal Charge Must First Be Made.—Such charge must be in writing, signed by the accuser, and if made by a person other than a member of the Society must be sworn to before an officer of the State of California authorized to administer oaths. Charges must state the acts or conduct complained of with reasonable particularity.

"(2) Charges.—Filing.—Secretary's Duties.—Presentation to Board of Directors (or Grievance Committee).—Charges must be filed with the secretary of the accused member's society. At the first regular or special meeting of the Board of Directors of such component county society held after charges are filed, the secretary must present said charges to the Board. The Board of Directors shall then or at any adjournment of said meeting, but not more than thirty days after the date of such regular or special meeting, consider the charges, and in its discretion determine whether or not further proceedings shall be conducted. If the Board determines that no further action shall be taken, the charges shall be dismissed.

Mr. Speaker, I move that between the words "members and society" in the third line of this paragraph the words "component county" be inserted.

Vice-Speaker: You have heard the motion. Is there a second?

Doctor Mentzer of San Francisco seconded.

Vice-Speaker: Is there any debate? All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"If a component county society has no Board of Directors and more than ten members, its members must, at a regular meeting of the Society, elect a grievance committee of not less than five (5) active members in good standing; two members shall be designated by the Society to serve for a period of one year, two members shall be designated to serve for a period of two years, and one member shall be designated to serve for a period of three years. At the expiration of the terms of office of the respective members of such committee, successors shall be elected in like manner to serve for a period of one year each. Such grievance committee shall exercise all the power and perform all the duties herein conferred upon boards of directors in the manner and within the times herein provided. If a society has less than eleven members, the entire society, exclusive of the accuser and accused, shall constitute the grievance committee. All references herein to board of directors shall be deemed to include boards of councilors, grievance committees, and component county societies of ten members or less."

Mr. Speaker, between the words "councilors" and "grievance committees" in the next to the last line of that paragraph, I move that we insert the words "and such."

Vice-Speaker: You have heard the motion. Is there a second? Doctor Howson of Los Angeles, seconded the motion.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(3) Service of Charge Upon Accused.—If the Board of Directors determines that further action, with respect to said charges, shall be taken, the Board must, within fifteen (15) days after such decision, cause a copy of the charges to be served upon the accused by personally delivering a copy thereof to him, or by depositing a copy thereof in the United States mail, registered and addressed to the accused either at his last known office or at his last known residence.

"(4) Time and Place for Hearing.—Service of Notice Thereof.—The Board of Directors shall, at said meeting at which its decision to proceed is made, fix a time and place for a hearing of said charges. Written notice of the time and place set for the hearing shall be served upon the accused within fifteen (15) days by personal delivery or registered mail."

Mr. Speaker, at this point I move the insertion of the words "as aforesaid."

Vice-Speaker: You have heard the motion. Is there a second? Motion seconded by Doctor Kelly of San Francisco.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"The time so set for a hearing shall be not less than fifteen (15) days after the accused has been served, as aforesaid, with a copy of the charges and with the notice of the time and place set for the hearing; said hearing must be held within the county in which the accused holds his county society membership. The hearing before the Board of Directors must actually commence within *six months* from the date of the filing of written charges. Failure to comply with this requirement shall constitute an automatic dismissal of the charges.

"(5) Right of Accused to Answer, Time to Answer, Formal Requirements.—The accused may, not less than five (5) days before the time set for a hearing, answer said charges. The answer shall be in writing and the original and three copies shall be filed with the secretary of the Society, provided, however, that the failure of the accused to answer shall not be deemed to be an admission of the truth of the charges or a waiver of the accused's right to a hearing with respect to said charges."

We try to protect a man and at the same time to see that justice is done in other respects.

"(6) Rules Governing Hearing.—Duties of Referee of Society, Advice As to Procedure Only.—The Board of Directors shall give ample opportunity both to the accuser and the accused to be heard in person, and to present all testimony, evidence, or proofs which the accuser or the accused may deem necessary, provided that the Board may reject all testimony, evidence, or proofs, which in the judgment of the Board, are immaterial, irrelevant or unnecessarily repetitious. Neither the accused nor the accuser shall be represented by an attorney-at-law."

Mr. Speaker, I move that the last sentence "neither the accused nor the accuser shall be represented by an attorney at law" be stricken out.

Vice-Speaker: You have heard the motion. Is there a second? The motion was seconded.

Vice-Speaker: All those in favor will signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"The Board in its discretion may be represented by a referee appointed by the Council or Executive Committee of this Association (that is the C. M. A.) to advise the Board, the officers of the Society, the accuser and the accused, with respect to procedure only. It shall be the duty of said referee to answer all procedural questions submitted by said persons and, on his own initiative, to call attention to any procedural errors."

Mr. Speaker, I move the insertion between the words "referee" and "appointed by the Council" of the following: "who may, but need not, be a member of this Association, and who shall be."

Ordinarily the councilor of the district would serve as such a referee, but we feel that it may be that the society or the accused might desire an attorney. If so, it would be their privilege to have one.

Vice-Speaker: You have heard the motion. Is there a second? The motion was seconded.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(7) Record of Proceedings.—Shorthand Reporter Discretionary.—Duty of Secretary to Preserve Record.—Right of Accused to Copy.—The secretary shall preserve the original of said charges with a certificate of personal delivery or of mailing of a copy or copies thereof, as the case may be, the original notice of the time and place set for the hearing with a certificate of personal delivery or of mailing of a copy or copies thereof, as the case may be, and the original of the answer filed by any member accused if an answer be filed. At the hearing, the Board of Directors may, in its discretion, and at the expense of the Society, employ a competent shorthand reporter to record and transcribe into typewriting testimony adduced on behalf of the accuser and the accused. If the Board shall decide not to employ a reporter, then the secretary of the Society shall be present and shall keep and prepare a summary of all testimony adduced. The original charges with certificate of service thereof, the original notice of time and place for hearing with certificate of service thereof, the answer or answers, may be filed, if any be filed, all documentary evidence introduced at the hearing, all typewritten transcript of the testimony or the secretary's typewritten summary, and the written decision of the Board of Directors shall constitute the record of the entire proceedings. The secretary shall, upon receipt of a sum sufficient to defray the cost thereof, cause a copy of such record to be transcribed and furnished to the accused. The secretary shall keep such record and, in the event of an appeal to the Council of this Association, shall, upon the request of its secretary, transfer said record to the Council."

"(8) Decision of Board. — When Must Be Written. — Rules Governing Vote of Board.—The Board of Directors, after having given the accuser and the accused member full opportunity to be heard, shall conclude the hearing and shall render its decision in writing not more than thirty (30) days thereafter. Hearing shall include any oral arguments and the filing."

Mr. Speaker, at this point I move we insert the words "and consideration."

Vice-Speaker: You have heard the motion. Is there a second? Doctor Hamlin seconded the motion.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"and consideration of any written briefs. The Board of Directors by a two-thirds affirmative vote of all of the eligible members of the Board present and voting may exonerate or may censure, suspend or expel the accused member as the facts in its opinion may justify."

Mr. Speaker, at this point I desire to move the insertion of the following: "The decision of the Board of Directors may be expressed in resolution adopted by said vote. The decision may not contain an opinion and need only be signed by the secretary or the acting secretary of the component county society."

It was moved, seconded and ordered, that the amendment be accepted.

Doctor Roblee:

"The failure of at least two-thirds of all the members of the Board of Directors present and voting to agree upon the disposition of the charges shall act automatically as a dismissal of the same. No member of the Board of Directors not present at the said hearings for the entire time thereof shall be entitled to vote with respect to the disposition of the charges."

"(9) Suspension. — Maximum Period. — Status of Suspended Member.—If the Board of Directors shall determine to suspend an accused member, the term of such suspension shall be within the discretion of the Board, provided that in no case shall a member be suspended for a period greater than one year. A suspended member shall have no rights or privileges in the Society, provided that at the expiration of the period of suspension such suspended member shall not be reinstated to membership in good standing until he applies for reinstatement and pays all dues accrued during said period of suspension."

"(10) (a) Board's Decision.—Secretary to Send Copies.—Within ten (10) days after the decision of the Board of Directors, the secretary of the Society shall transmit a copy of the decision to the Board, to the accused member or members and to the secretary of this Association."

"(b) Board's Decision Final.—Subject to Appeal.—The action of the Board of Directors of a component society shall be final, subject only to appeal to the Council of the California Medical Association in such cases as are provided in these by-laws."

Mr. Speaker, I move the insertion at this point of the following: "The decision of the Board of Directors shall not become effective until the expiration of ten days after time during which an appeal may be taken to the Council of this Association. Filing an appeal with the secretary of this Association shall automatically stay the execution of the decision of the Board of Directors of the component county society until written notice of the action of the Council of this Association with respect to appeal has been received by the secretary of the component county society from which the appeal was taken."

Vice-Speaker: You have heard the motion. Is there a second? Doctor Toland of Los Angeles seconded the motion.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"(c) Technical Rules of Evidence Not to Govern Disciplinary Hearings.—All hearings with respect to the disposition of charges against a member of a component county society shall be held and conducted in such manner as to ascertain all the facts fairly to the accuser and accused, eliminating all formal or technical rules and requirements which ordinarily pertain to judicial proceedings."

"(d) Members Agree that No Cause of Action Shall Accrue.—Any person so charged, censured, suspended, or expelled shall have no claim or cause of action against this Association, a component county society or any member, director, councilor or officer, thereof by reason of such charges, or the hearing or the consideration thereof or censure, suspension or expulsion therefor."

That would not prevent a suit being filed. You can file a suit for almost anything, but it would certainly go a long way in court in the protection of a member.

"(e) Expelled Members.—Right to Apply for Membership.—When Accrues.—Any person whose membership has been involuntarily terminated in a component county society by reason of violation of these by-laws may apply for membership after the expiration of one year from the date said membership was terminated, and such application shall be considered in the same manner as a new application for membership."

"Section 4. Procedure for Appeal to Council.

"A member of a component county society censured, suspended or expelled by his county society may appeal from the action of such component county society to the Council of this Association within the period of two months succeeding the date of such censure, suspension, or expulsion. Appeals shall be in writing and be filed within the said period of two months in the office of the secretary of this Association. Upon the filing of an appeal the secretary shall present it to the first subsequent meeting of the Executive Committee or the Council. Appeals shall be heard by the Council only after reasonable notice in writing of the time and place of the hearing of the appeal has been given to the appellant member and the president and secretary of the component county society."

Mr. Speaker, I move that after the word "notice" in the third to last line that the words "of not less than ten (10) days" and following the last word, "society," "as provided in Section 3 hereof" be inserted.

Vice-Speaker: You have heard the motion. Is there a second? Motion seconded.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Doctor Roblee:

"Section 5. Rules Governing Appeals.

"In hearing appeals, the Council shall review all questions of procedure, and may, in its discretion, review the evidence contained in the record of the original proceedings held before the Board of Directors of the component county society. The Council may make findings of fact contrary to, or in addition to, those made by said Board of Directors. Such findings may be based on the evidence adduced before said Board of Directors, either with or without the taking of evidence by the Council. The Council may, for the purpose of making such findings or for other purpose in the interest of justice, take additional evidence of or concerning facts material to the questions involved, or may, for such purpose, appoint a committee of its members or any notary public to act as referees or referee for the taking of such additional evidence."

Mr. Speaker, at this point I desire to transpose paragraphs. The second paragraph of rules reading:

"Such referee or referees shall render a report in writing to the Council, which report shall contain a clear statement of the facts found by the referee or referees from the testimony or evidence adduced."

"The Council shall use any lawful means which in its judgment will best and most fairly present all the facts involved."

That paragraph goes farther up where it belongs.

Motion seconded, vote taken and amendment duly ordered.

Doctor Roblee:

"The Council may affirm, reverse or modify the decision of the Board of Directors or make such other disposition of the proceedings as it may deem proper."

"In every case of an appeal the individual councilors and the Council, through a committee thereof, prior to any hearing being held upon the appeal, shall exert all proper efforts at conciliation and compromise."

"Neither the appellant member nor the component county society shall be represented by an attorney-at-law."

Mr. Speaker, I move the deletion of the last sentence. Motion seconded, vote taken and change in amendment duly ordered.

Doctor Roblee:

"This Association may be represented by its attorney to advise the Council upon procedural questions only."

"The decision of the Council shall be final and bind the appellant member and the component county society."

Doctor Roblee: Gentlemen, there is a clear track to be followed. I move, Mr. Speaker, the adoption of the by-laws as amended.

Vice-Speaker: You have heard the motion. Is there a second? Motion seconded.

Vice-Speaker: All those in favor signify by the usual sign.

Vice-Speaker: It is so ordered.

Thank you, Doctor Roblee.

(The Speaker returned to the chair).

Committee Appointments

The Speaker: We have now the announcement and approval of members of standing committees selected by the Council.

Mr. Speaker, the secretary speaking. Before making this announcement, I would like to inform the members that by 5 o'clock this afternoon 1,098 members had registered and seventy-one guest doctors from this and other states; there were sixty-seven exhibitors; there were 346 members of the Auxiliary. The total registration at 5 o'clock was 1,582.

Mr. Speaker, I am directed by the Council to transmit to the House its nomination of the following appointees for the standing and special committees of the Association:

Committee on Associated Societies and Technical Groups, Dr. William G. Geistweit, reappointed.

Committee on Health and Public Instruction, W. R. P. Clark, San Francisco, reappointed.

Committee on History and Obituaries, J. Marion Read of San Francisco, reappointed. Dr. Frank R. Makinson of Alameda County is made the chairman of the committee.

Committee on Hospitals, Dispensaries and Clinics, Daniel R. Crosby of Oakland, reappointed.

Committee on Industrial Practice, Mott R. Arnold, San Diego, reappointed.

Committee on Medical Defense, Fred R. De Lappe of Modesto, reappointed.

Committee on Medical Economics, William R. Molony, Sr. of Los Angeles, reappointed.

Committee on Medical Education and Medical Institutions, Loren R. Chandler, chairman, reappointed.

Committee on Membership and Organization.—At the request of Doctor McGavack, who desires to be relieved from committee duty, the Council nominates and transmits the name of Dr. Don L. Pratt.

Committee on Postgraduate Activities, Clarence G. Toland, reappointed as chairman of the committee.

Committee on Publications, Oscar Reiss of Los Angeles, reappointed.

Committee on Public Policy and Legislation.—Replacing Fred R. De Lappe of Modesto, T. Henshaw Kelly of San Francisco.

Committee on Scientific Work, Secretary of the Section on General Medicine and Secretary of the Section on General Surgery. Their names have not yet been transmitted to the secretary. The President of the Association nominates and recommends the appointment of the following three members to fill the terms of members whose terms of office has expired:

Harold Brunn of San Francisco; Henry J. Ullman of Santa Barbara; Clarence G. Toland of Los Angeles.

The Speaker: You have heard the report of the Council in this matter. What is your pleasure?

Dr. S. H. Mentzer, San Francisco, moved and Doctor Anderson, Fresno, seconded that the appointments be approved.

The Speaker: All those in favor say aye.

* * *

Report of Reference Committee No. 1: On Reports of Officers and Committees

The Speaker: We will now have the report of the Reference Committees. Reference Committee No. 1 on the Reports of Officers and Committees. I recognize Dr. Eric Larson, chairman of the committee.

Doctor Larson: Mr. Speaker, members of the House of Delegates: Your Reference Committee on Reports of Officers and Standing and Special Committees desires to present the following report to the House of Delegates for its approval.

Doctor Larson read the report, which was accepted as read and as follows:

Mr. Speaker and Members of the House of Delegates: Your Reference Committee on Reports of Officers and Standing and Special Committees desires to present the following report to the House of Delegates for its approval:

Report of the President.—Your Reference Committee commends President Peers for having conducted the affairs of the Association in a most able manner. He has visited every corner of the state, and has brought cheerfulness to and closer coöperation between the component societies and the parent body. It is leadership such as this that makes for progress and unity in the affairs of the California Medical Association. He has stressed the necessity for enlarging our membership to include many qualified physicians who should take an active part in our organization. Your Committee recommends that every county society should be visited in like manner each year by the officers, to obtain an increasing measure of the coöperation which our president has this year received.

Report of the President-Elect.—It is the Reference Committee's opinion that our president-elect is completely qualified to carry on the work in a manner as efficient as has his predecessor. He has had many years of active and constructive leadership in our association and at this particular time we are most fortunate in having such an individual to carry on the affairs of our organization. We feel certain that he will choose able and efficient committee members to assist him in the solution of difficult problems.

Report of the Council.—In reviewing the financial report of the Society for the past year it is obvious that the expenditures have been so far in excess of the resources that careful consideration will be necessary in the future in order that our financial status may increase its security. The financial statement of this last year reveals a deficit. This deficit was largely due to the demands of the House of Delegates upon the Council. In the future, careful consideration by the House of Delegates should be given to any expenditures in a sum larger than the annual income, in order that a proper balance be maintained in the treasury. The surplus, which is less than it has been for a number of years, should be increased as rapidly as possible to meet such emergencies as will occur.

During the past year our secretary-treasurer, by able and efficient management of our medical association, has saved $12,641.98, for which he is to be commended. Your Reference Committee feels that as our organization increases, even greater savings and earnings may be effected.

This committee believes that the Council acted judiciously in avoiding a possible expenditure of $35,000 in the Qualifying Certificate Law, and is to be commended for this action.

The Reference Committee approves the Council's recommendation to increase the annual dues to $15 a year.

Bearing in mind the ever-important matter of economy, we believe that the expense incurred by one annual meeting of the county secretaries, which is not excessive, is probably justified.

Appeals.—Your Reference Committee commends the Council's advice to have consultation with the district councilor and the secretary of the California Medical Association in matters where disciplinary action is contemplated by any county society.

Malpractice Insurance. — The Reference Committee thanks the Council for its efforts in making an extensive study by the Council and a special committee on the problem of malpractice insurance.

Amendments.—Your Reference Committee presents an amendment to the By-Laws introduced by the Council which may properly advance the expanding functions of the Association to insure efficiency. It provides that the chairman of the Committee on Postgraduate Activities be a member of the Public Relations Committee. The amendment reads as follows:

Resolved, That Section 20 (a) of Chapter V of the By-laws of this Association be and is hereby amended by adding after the phrase "The Committee on Industrial Practice and the Cancer Commission" and before the phrase "and the President," contained in the first paragraph of said Section, the following:

"The Committee on Postgraduate Activities."

Proposed Amendment to Constitution:

Your Reference Committee presents an amendment to the Constitution, introduced by the Council. This amendment places the immediate past president on the Council for the period of one year. Your Reference Committee recommends the adoption of this amendment, because we think that the experience gained by the president while visiting every component county society in the State of California is of invaluable aid in the solution of problems which may develop in the subsequent year.

This amendment cannot be finally passed until the next annual meeting of the House of Delegates.

The amendment reads as follows:

Resolved, That Section 1 of Article VII of the Constitution of this Association be and is hereby amended by inserting in the first paragraph thereof after the words "the president" the following:

"The past president"; and, be it further

Resolved, That Section 8 of Article VII of the Constitution of this Association be and is hereby amended by inserting after the words "the president" the following:

"The past president"; and, be it further

Resolved, That Section 1 of Article X of the Constitution of this Association be and is hereby amended by inserting after the words "a president" the following:

"A past president"; and, be it further

Resolved, That Section 2 of said Article X of the Constitution of this Association and the title thereto be amended to read as follows:

"Section 2—President-Elect, when and how elected; term of office. Past president.

"The House of Delegates at the regular annual session thereof shall elect the president-elect to serve until the adjournment of the final meeting of the House of Delegates at its next regular annual session. At the conclusion of the final meeting of the House of Delegates at its next regular annual session, such president-elect shall assume the office of president, and serve as such for the term of one year thereafter, or until his successor assumes office.

"At the expiration of his term of office the president shall become the past president and serve as such for a term of one year thereafter, or until his successor assumes office"; and, be it further

Resolved, That Section 4 of Article X of the Constitution of this Association be and is hereby amended by inserting in the first paragraph thereof after the word "president" the following:

"Past president."

County Hospitals.—The report concerning county hospitals is of such vital interest, and entails so much thought and judicious action that the Reference Committee does not feel that it is wise enough to make any particular comment, except that the Council continue to exert its best efforts in whatever manner it sees fit, even though it entails unexpected expenditures. We believe that every member of the House of Delegates who is alive to this problem, well explained by Mr. Siemon at the Monday evening meeting in a lengthy and comprehensive digest in its several phases, will support the Council in its activities in this regard.

Hospital Insurance.—Your Reference Committee approves the activities of the Council in regard to the hospital insurance problem. This phase of projected socialization, involving as it does so many schemes promoted by laymen at the expense of our profession, requires diligent and comprehensive consideration on the part of the medical profession. In order to solve the problem we feel that a plan should be presented which would not only make x-ray and laboratory functions those of a doctor, but would explain how he is to be paid. We recommend that the Council work out a plan or plans with the coöperation of the hospital and the specialists concerned. We approve of the Council's desire to have a fundamental plan which would be workable in its main tenets in all counties. However, we also realize that a problem in one county may not be applicable to another county. This may be because of the difference in the geographic location, the political situation at the moment, the resources of the people of the county and the energy of the individual medical members of that county in upholding the standards of the State Medical Association.

Committee on San Diego Exposition Exhibits.—Every thinking observer of the medical exhibit at the Exposition realizes the educational value to the layman of what the doctor is trying to do in his professional activities for the sick. The Council is to be especially commended for this display. Your Reference Committee feels that the individual members of the committee who were appointed by the Council to make this display possible, should not suffer financial hardship because of the duties which they have so faithfully performed. It is understood that the Exposition will probably repay the committee for its expenses. If, however, there is a failure in this regard, this Reference Committee recommends that the California Medical Association repay these members for their expenses. The Reference Committee further recommends that the Council continue to show increasing interest in scientific exhibits to be used at meetings and expositions.

Committee on Scientific Sections.—The Reference Committee recommends that further time be allotted to formulate a more satisfactory arrangement for the annual program, looking toward consolidation of section meetings, at the same time permitting each specialty to have an organization to preserve its entity. The general sections should have the advantage of hearing their technical papers.

Report of the Speaker of the House of Delegates.—We compliment the Speaker on the dignified manner in which he presides. "The gavel is used sparingly and the gavel is used impartially, but when occasion arises, the gavel is used with authority." We recommend that the gavel be presented to the Speaker at the termination of his office as a token of our esteem. We recommend also that the previous speaker be presented with a similar token of our appreciation.

Report of the Secretary-Treasurer.—We believe that our organization is fortunate in having procured the services of a nationally known man who is not only an outstanding physician, but is also a distinguished secretary. Through his efforts the business of the Association has been organized to meet the ever-increasing demands, resulting in greater efficiency and economy.

The committee reviews with alarm the rapidity with which our financial resources have been depleted in carrying out the instructions of the House of Delegates during the past two years. We would again call your attention to the fact that the Council has been compelled to dispense rapidly our funds to comply with the action of the House of Delegates.

Report of the Editor.—Our official journal is continuing its high standard and remains one of the best state medical publications of the nation. The editor has frankly stated that it is unfair for the Association to impound all papers given at the annual meeting, necessarily delaying the publishing of the selected papers from one to two years. There are forty-five papers remaining unpublished from the last annual meeting. The Reference Committee therefore recommends that the editor be allowed to enlarge his journal to sufficient proportions to allow publication.

Report of the Legal Department.—The report of the Legal Department is comprehensive, and entails problems of importance in safeguarding the practice of medicine in our state. We are unable to criticize in a legal manner any of the activities concerned in this report. We feel assured that the same energy and interest will be continued. We congratulate our Legal Department on its past year's endeavor.

Report of the Councilors.—These reports, as presented in the Pre-Convention Bulletin, should be thoroughly studied by the delegates in order to realize the immense amount of unselfish devotion these men have given in performing their duties.

Report of the Woman's Auxiliary. — The Woman's Auxiliary in its activities is one of the important adjuncts of our organization. This is especially true in the larger cities where concerted action and coördinated activities can be accomplished. Each succeeding year proves to us the importance of our coöperation and encouragement. They stand ready to help in any deleterious problem that affects the practice of medicine and the Reference Committee is happy to endorse all of their activities.

Committee on Health and Public Instruction.—Your Reference Committee endorses the work that has been carried on by this important committee and hopes the financial condition of the Association in the future will be such that their program can be enlarged and enhanced.

Report of the Committee on History and Obituaries.—We are grieved to know that thirty-seven of our fellow members have passed from us during the year. The Reference Committee asks that the members of the House of Delegates arise as a mark of respect to those who have died. We commend the committee for initiating a plan for the collection and preservation of medical history throughout the state.

We recommend to the House of Delegates that the secretary arrange for a suitable memorial tribute at the first general session of each annual meeting.

Report of the Committee on Hospitals, Dispensaries and Clinics.—We note that this committee reports that their work has been covered by the Public Relations Committee. We recommend this continued association.

Report of the Committee on Industrial Practice.—This is an important committee and the recommendations which they are offering to the House of Delegates should be carefully studied. The committee must continue unhampered in its activities relating to industrial practice.

Report of the Committee on Medical Defense.—This committee has presented a comprehensive survey for the California Medical Association. The conclusion is that it would cost us as much or more to underwrite our own company as to continue with the existent arrangements. In consideration of the present policies with private companies, it seems logical to continue without change. However, with the information at hand the committee should be vigilant to detect unsatisfactory changes in the policies or premiums, with the thought that we can always establish our own coverage satisfactorily to all concerned and with a tendency to be nearer the non-revocable insurance than in the present form.

Report of the Committee on Membership and Organization.—We approve the findings of the executive group of this committee.

Report of the Committee on Postgraduate Activities.—The importance of this committee has been felt in several smaller communities throughout the state. The present chairman has offered many suggestions to the speakers which are making the meetings more practical. We recommend the continuance of this activity.

Report of the Committee on Public Policy and Legislation.—Public policy and legislation, as handled by the committee, remains the keystone of our profession in California. We cannot conceive of any one who can give other than constructive criticism when one realizes the problems that must be solved in diverse manners and unusual ways. We are sure that every member of our Association is grateful, and that a large percentage do not realize the sacrifice of time, money and health, in trying to protect our profession against the inroads directed against the best interests of the public's health and against the California Medical Association. We should assure this committee that we stand ready individually and collectively to answer any call for help.

Report of the Committee on Scientific Work.—The recommendations as outlined in this committee's report have already been dealt with in the report of the Council.

Report of the Committee on Public Relations.—A study of this report will demonstrate its wide scope and importance. The recommendations with which they conclude their report should be studied and action taken. The Reference Committee feels that the recommendations made have been, in a large extent, carried out in the larger centers. We are certain that much has been accomplished, and that more will have to be done. Your Reference Committee commends wholeheartedly this report.

Report of the Committee on Medical Education.—In view of the fact that the American Medical Association and the American Federation of Medical Colleges have created established standards to be met by institutions in order to qualify as acceptable for medical and intern training, your Reference Committee sees no reason why the state committee should be burdened with these duties which are now being discharged by the central organization.

Report of Committee on Budget.—The budget having been approved, in concurrence with the provision of the Constitution and By-Laws, by the committee and the Executive Committee of the Council, your Reference Committee recommends that it be approved and adopted.

Report of the Committee of Five.—The Reference Committee is not making any comments upon the report of the Committee of Five, in view of the fact that the Council has declared its position, which will be given to the House tonight.

The Committee of Six.—The work of the Committee of Six is done. It has performed the duty which was assigned to it at Yosemite. We recommend that the committee be discharged.

Report of the Committee on Tax-Supported Hospitals.—The Association appreciates the vast amount of work and time that have been devoted to this most important problem of the Association. We commend its contribution in affording us a better understanding of the situation which will be extremely helpful in solving the problems when they appear, probably in the fall elections. We approve the comment of the Council, which is as follows: "The Council believes that this initiative contains the seeds of the most dangerous and fundamental changes in the practice of medicine ever presented to us and urges that every facility be granted to oppose this initiative and that every effort be put forth by the physicians of California to prevent this proposed ruin of medical practice."

Cancer Commission. — The résumé, appearing in a printed pamphlet, summarizes the labor of this commission for the past two years. It is a distinct contribution to our profession. We heartily recommend that the Cancer Commission devote its efforts, by meetings and scientific exhibits, toward the education of the doctors in the smaller communities on the subject of cancer.

Report of the Committee on Scientific Exhibits.—The scientific program as evidenced by exhibits has been gaining in importance each year. Greater emphasis should be given the work of the Committee on Scientific Exhibits. The committee should strive to increase the scope of its work, to the end that the exhibits will replace numerous formal discourses. The subjects should be presented as exhibits with the same recognition and privilege of publication as is accorded to scientific papers. This may help to solve the problem of the unpublished papers and aid in concentrating the program into fewer sections.

Report of the Committee on Scientific Sections.—This committee can convene with the Committee on Scientific Exhibits. Their coöperative effort will concentrate our numerous sections, permitting more unity in the various branches at our annual meeting. The Council and secretary may eliminate the necessity for space for the smaller sections at each annual meeting.

* * *

This meeting at Coronado will long be remembered as one of great educational value, important business accomplishment and enjoyable good fellowship. This House of Delegates tenders its sincere thanks to the Committee on Arrangements for its well conducted efforts which have made this possible.

Respectfully submitted,
E. ERIC LARSON (Chairman),
ALFRED L. PHILLIPS,
NATHAN G. HALE.

* * *

Report of Reference Committee No. 1.—The chairman of the committee read each section of the foregoing report. Motions were duly made and seconded that each section be adopted. At the conclusion of the report, the chairman of the committee moved that the report be adopted as a whole. This motion was seconded and carried.

* * *

Reference Committee No. 2: On New and Miscellaneous Business and Resolutions

THE SPEAKER: The chair recognizes Dr. Daniel Crosby, chairman of the Committee on Resolutions.

* * *

DOCTOR CROSBY: We have numbered these resolutions in the manner in which they were received, and I shall read No. 1 first.

Resolution No. 1: On Hospital Insurance; Exclusive of Medical Services

WHEREAS, Certain proponents of hospital insurance schemes have made misleading statements regarding the attitude of the California Medical Association towards certain aspects of health and hospital insurance; and

WHEREAS, Such statements are entirely unwarranted and unfounded, and would seem to be intentionally misleading; now, therefore be it

Resolved, That this House of Delegates reaffirms its belief in and endorses the policies established by the 1935 House of Delegates, by the Council and by the Department of Public Relations of the California Medical Association on matters pertaining to hospital service insurance; and be it further

Resolved, That radiology and pathology being in all of their several parts and subdivisions the practice of medicine, shall be excluded in their entirety from the benefits included in hospital service policies.

Your committee thought it advisable to modify the text of this resolution as follows:

WHEREAS, Misleading statements have appeared and uncertainty appears to exist regarding the attitude of the House of Delegates, the Council of the California Medical Association and the California Medical Association toward certain aspects of hospital insurance; and

WHEREAS, It is deemed advisable to reiterate and emphasize the position of the House of Delegates, the Council and the California Medical Association; therefore be it

Resolved, That this House of Delegates reaffirms its belief in and endorses the policies established by the 1935 House of Delegates, by the Council and by the Department of Public Relations of the California Medical Association on matters pertaining to hospital service insurance; and, be it further

Resolved, That radiology and pathology, being in all of their several parts and subdivisions the practice of medicine, shall be excluded as such from the service benefits of hospital service policies.

In this form, Mr. Speaker, the committee recommends its adoption.

THE SPEAKER: The question is upon the adoption of the substitute resolution. Is there any debate?

The Speaker recognizes Doctor Wilson of Los Angeles.

DOCTOR WILSON: I had hoped that we all understood the principles involved in attempting to sell professional services as a part of the hospital insurance certificate, as we seemed to have fought that issue out at Riverside. The committee's modification of the original resolution in using technical evasion providing for means of reimbursement for professional services is going to lay us open to the fact that when certificates are offered to the public by solicitors, and through advertisements and the beneficiaries who provide a professional service, the radiologists and pathologists will definitely open the way to selling professional services by solicitation and advertising, and will violate the code of ethics. It seems to me that an adherence to a definite separation of professional services and hospital services must be maintained, and that any attempt to evade the issue is going to lead us directly into the most outrageous, cut-throat competition in the practice of medicine that will not only follow for payment of the radiologists, the pathologists and laboratory services, but will extend all the way down the line, whether the certificate be sold by a corporation, insurance company or any little outcast hospital group; and when the California Medical Association approves the principle whereby professional services may be compensated for as the result of solicitation, we have opened the door to that type of competition in all directions. (Applause.)

THE SPEAKER: Is there further debate on this subject?

DOCTOR GIBBONS (San Francisco): I ask that we hear from Mr. Peart on this subject.

MR. PEART: The report of the committee in recognizing that cash benefits may be paid to the patient for the cost of these professional services is, I think, a legal disposition of the question. The point made by Doctor Wilson is that, ethically, the service should not be sold in that manner. Some time ago, a few weeks I think, we wrote a letter to a roentgenologist of Sacramento, Doctor Graham, in which we expressed the view of the Council that cash payments and cash indemnities for these services paid to the patient were approved by the Council. I do not think we have that letter with us, but it was carefully read to the Council and its approval was obtained before the letter was sent. The question, however, is one of ethics. If the Association decides as Doctor Wilson argues, then, as Alameda County has determined, no professional services whatever will be included. It is perfectly legal, I think, to include them as reported by the committee. Solicitation, legally, is not involved under a decision of the District Court of Appeal, but, ethically, that is your determination and not mine.

DOCTOR ULLMANN (Santa Barbara): I think it would be wise for us to use the same terms that we used in the Council meeting in regard to this, or the term "reimbursement" instead of "cash benefits paid to the patient." If I remember, Mr. Peart at that time said it was legal to reimburse policy holders for money expended, that is, losses, and that in this particular type of reimbursement they could only receive it on the presentation of a paid or receipted bill.

THE SPEAKER: Is there further debate? If not, the question is on the adoption of the amended resolution.

THE SPEAKER: Doctor Kelly of San Francisco.

DOCTOR KELLY: I think I have had my neck out as far as anyone in this whole business and I think we should spend just a minute looking at this problem and the result of this resolution as it will affect possible hospitalization plans evolved either by county medical societies or by hospitals. If we limit this at the present time to no such services in any policy in any plan which will get our approval, we may delay the development of plans which are under way in certain parts of the state. I think we ought to consider for a minute just what this reimbursement to patients for the cost of these services means, and consider just how it is going to result in ruthless solicitation and debasement of practice. The question that was decided on was that of a policy considered by the Inter-Coast, in which they said they would provide cash indemnities for the cost of x-ray and laboratory services. The patient who was to buy the policy had free choice of as many hospitals, I think, as Inter-Coast could sign up in the neighborhood, and he had free choice of roentgenologists, as far as free choice of roentgenologists can be had. One has free choice of hospitals in a big community or a more limited choice in a small community. In the matter of a plan which might provide service anywhere in the state for a policy holder, the free choice of physicians, roentgenologists and clinical pathologists involved here would be fairly broad. The fact that the roentgenologist or the clinical pathologist was in the hospital which the patient chose would limit the choice to that extent only. The Pacific Employers, as we all know, issued a policy a while back in which it was going to indemnify the patient for medical services rendered, but the policy provided that only certain doctors could perform these services if the patient was to be indemnified. The Appellate Court held that that was in effect the practice of medicine, because in the application for the policy the patient signed an agreement making the company his agent to pay the money to the doctor. In that kind of policy, unquestionably everything Doctor Wilson suggests would happen and would happen in the worst way. The Pacific Employers did not follow that case through. It left it in the Appellate Court and is now putting out sample policies at least, which provide for straight cash indemnification up to specified amounts in the policy, to any doctor that the patient may choose to have to take care of him, provided only that the doctor be a member of the county society in the county in which the service is rendered.

I think we should consider what our attitude would be toward a policy like that. We do not have to approve any plan unless the provisions of that plan suit us, but it would seem to me, in fairness to some of the hospitals that are trying to get along and have to sell these policies in competition with lay groups, that we might leave the door open on this one business, provided that every plan that comes up for approval by the state society be required to have that type of free choice of physician in it. I am not so sure that we ought to limit ourselves fixedly to absolutely no provision for any kind of care of this type in a policy because it may be, one of these days, that one of the companies or one of the county organizations will find that it has to include some consideration for those services. I have a feeling somehow that if we only approve the right plan we may let them do that, still approve the plan and still not have the professional suffer.

The Speaker: Doctor Goin of Los Angeles.

Doctor Goin: I think that the purpose of this resolution is not to close the door to some proper method of including some degree of medical care with hospitalization insurance plans. The purpose of the resolution is primarily to answer certain persons who have publicly stated in printed and written material that the California Medical Association has never spoken on these matters, and who take the utterances that the California Medical Association has made and wheezeled them into things they were never meant to say. Therefore, this resolution was prepared with some attention to its detail, so that it will be practically impossible for any honest person to say that the California Medical Association has not pronounced authoritatively on these matters which are in question.

If we do not include in this resolution a clause which provides specifically for indemnification, we have not particularly closed the door to indemnification. We have simply left the matter in suspense, and indemnification can, if desirable, be arranged with hospital service insurance corporations or other corporations which show a disposition to write a decent policy and not to include medical care in it. I will remind you that you leave the door open this way by including the last clause proposed by the Reference Committee, and that we could just as well add a clause saying that the patients should be indemnified for appendectomies, obstetrics, etc. I do not see how we can differentiate between one medical branch and another. To eliminate this last clause will not weaken the hospital's position when it attempts to sell hospitalization insurance. I wish all of you could have heard Doctor Kelly when he defined hospital service as consisting in the bedding, the boarding and the washing of patients, and the performance of such things as could not be performed in a doctor's office. If we insist on those things and stand firm that hospitalization does not include medical service in any form, perhaps we will survive as practitioners of medicine.

Mr. Speaker, in behalf of the Los Angeles delegation, I move the amendment of the resolution as presented by the committee by the deletion of its last paragraph. (Applause.)

Doctor Askey: I second the motion.

Doctor Crosby: I suspect that the doctor did not mean to delete all of the last paragraph. I suspect that he meant to delete the last two lines, "except that lawful reimbursement to the patient for the cost to him of such service may be provided."

Doctor Goin: May I change my motion then, I having misunderstood the punctuation, to have it exclude that portion of the amendment beginning with the words, "except that," namely, exclude the last two lines?

The Speaker: The question is on the amendment to the substitute resolution, deleting the portion mentioned by Doctor Goin. If there is no further debate, all those in favor will say, "aye." The motion was regularly carried.

The Speaker: The question now is on the substitute resolution as amended. All those in favor will say, "aye." The substitute resolution was adopted as amended.

* * *

Doctor Crosby: The second resolution reads as follows:

Resolution No. 2: Concerning County Hospitals

Whereas, The report of the Committee on Tax-Supported Hospitals has shown conditions existing which make it the most serious problem confronting the medical profession of our state today, and since there are now being circulated petitions for an initiative law to open the county hospitals to all citizens, rich and poor alike, and since the proponents of this measure are committed to a program which apparently intends to include medical service with hospitalization, and since the proposed initiative law would confer such broad powers on the County Boards of Supervisors, that it threatens to bring upon us a form of socialized medical and hospital service which will ultimately be as unsatisfactory to the public as it will be unfair and unjust to the members of the medical profession of California; and

Whereas, It seems essential that a definite and acceptable agreement as to the proper function of a county hospital in relation to the profession be consummated; and

Whereas, The committee has prepared and presented a report which it believes represents to the best of its ability the situation which exists in this state, and since there has been no thought of alarming needlessly the members of this organization, but on the contrary, the committee feels that enough warning cannot be given concerning the gravity of the situation and since it is felt that it is imperative that a policy be developed in each component society which shall be uniform throughout the state in order that no one county shall adhere to a policy detrimental to another county or to the rest of the state; and

Whereas, The committee believes that grave disaster can be averted or its own interests advanced only by the highest degree of organization and the utilization of every facility at its command, and since we also believe that it is humanly impossible for any small group such as the members of this committee to function sufficiently often and continuously enough to be thoroughly efficient in so grave a situation, and knowing that this work must be done and well done if we are to succeed, therefore the committee requests that the following resolution be accepted and presented to the House of Delegates without prejudice or recommendation; therefore be it

Resolved: First, That the House of Delegates express its approval of the plan to place all hospitals in California under a central state board according to the plan proposed in recommendation number two in the committee report;

Second, That the House of Delegates approve the suggestion that each component society make a serious effort to correct any faults that may lie within its own ranks;

Third, That the president of the California Medical Association shall appoint a committee of six, three of whom shall be members of the standing committee on Public Policy and Legislation, together with three other members of the C. M. A. to continue the work of the reporting committee;

Fourth, That the Council of the California Medical Association shall be empowered to appropriate such funds and to employ such personnel as may, in their judgment, be necessary to effect a satisfactory solution of the county hospital problem;

Fifth, It shall be the duty of this committee to direct the effort of the C. M. A. to defeat the proposed initiative and to develop a unified county hospital program in the component societies that this committee shall report to the House of Delegates at its next annual meeting.

Doctor Crosby: After conference with the committee that submitted this resolution, it was decided to divide the resolution into two parts, one part to be presented with the recommendation of the committee for passing, and one portion to be submitted to the House without comment. The modified resolution No. 2 is as follows:

Whereas, The report of the Committee on Tax-Supported Hospitals has shown conditions existing which constitute the most serious problem confronting the public and medical profession of our state today with the present circulation of petitions for an initiative law to open the county hospitals to all citizens, rich and poor alike, and with the proponents of this measure committed to a program which apparently intends to include medical service with hospitalization and the conference of such broad powers upon the county boards of supervisors, that it threatens to bring upon us a form of socialized medical and hospital service which will ultimately be unsafe and inadequate for the public; and

Whereas, It seems essential that a definite and acceptable determination as to the proper function of a county hospital in relation to the public and the profession be consummated; and

Whereas, The committee has prepared and presented a report which it believes represents the situation which exists in this state, it is felt that it is imperative that a policy be developed in each component society which shall be uniform throughout the state in order that no one county shall adhere to a policy detrimental to another county or to the rest of the state; and

Whereas, The committee believes that grave disaster to the public can be averted by the proper dissemination of information pertinent to this subject, supported by the active interest and coöperation of the California Medical Association and every physician of California as a citizen; therefore be it

Resolved: First, That the House of Delegates recommends that each component society make a serious effort to correct any faults that may lie within its own jurisdiction.

Second, That the president of the California Medical Association shall appoint a committee of six, three of whom shall be members of the standing committee on Public Policy and Legislation, together with three other members of the California Medical Association, to make additional study of this question and to report from time to time to the Council.

Third, That the Council of the California Medical Association shall be empowered to appropriate such funds and to employ such personnel and take such action as may, in their judgment, be necessary to effect a satisfactory solution of the county hospital problem.

* * *

Doctor Crosby: At the request of the committee on Tax-Supported Hospitals your Reference Committee submits, without recommendation, the second portion of amended Resolution No. 2.

Be It Resolved, That the House of Delegates express its approval of the plan to place all hospitals in California under a control state board, according to the plan proposed in a portion of Recommendation No. 2 in the committee's report, which reads as follows:

"Since our present laws vest the supreme control over county hospitals in boards of supervisors composed of lay individuals, ignorant usually of hospital needs and management, and who often use this control to gain political power, and considering further that making a political football out of the county hospitals has in several counties resulted in inadequate care of the sick entitled to proper care at the county hospital, it is unanimously agreed that to remedy this situation it is necessary to eliminate politics and the present method of control by supervisors. Your committee, therefore, unreservedly recommends that an attempt be made to secure centralized control of all hospitals in the state. We recommend that a state control board be given the authority to regulate hospitals, and that each county operate under an advisory board appointed by and subject to the state board. This can be accomplished by amending the present public health law, vesting hospital control in the existing State Board of Health, thereby avoiding the creation of a new department or board.

"It is further recommended that (*a*) the details of such a plan be worked out by the Council of the California Medical Association and its Legislative Committee; (*b*) it be left to the discretion of the House of Delegates whether the attempt be made through the legislature or by an initiative act; (*c*) that this matter should be given preference and first consideration by the Council and House of Delegates over other legislative and initiative problems."

This, Mr. Speaker, is placed before you without recommendation.

The Speaker: It is placed before the House.

Doctor Wilson: If it is in order, Mr. Speaker, I move the tabling of this matter.

The matter was tabled.

Doctor Crosby: The third resolution follows.

Resolution No. 3: Regarding Payment for Hospital and Medical Services When Rendered in Automobile Accidents

Whereas, In the past, doctors and hospitals throughout California have rendered medical care to persons injured in automobile accidents, said persons being protected by public liability insurance and said injured persons having recovered damages and subsequently failed to reimburse the doctor and/or hospital; and

Whereas, The legal "set-up" at the present time offers no protection to doctors and/or hospitals against such practices; and

Whereas, Other states have adopted measures to protect doctors and hospitals under similar circumstances; now, therefore be it

Resolved, That the Council of the California Medical Association be instructed to take such necessary legal and/or legislative action to bring about protection to the doctors and hospitals of California under such circumstances.

Your committee, retaining the intent of the resolution, is offering a substitute resolution which differs merely in wording. It is:

Whereas, In the past, doctors and hospitals throughout California have rendered medical care to persons injured in automobile and other accidents, certain of whom are protected by pubic liability insurance and have recovered damages and subsequently failed to discharge their financial obligations incident to the accident; and

Whereas, The legal "set-up" at the present time offers no protection to doctors and/or hospitals against such practices; and

Whereas, Other states have adopted measures to protect doctors and hospitals under similar circumstances; now, therefore be it

Resolved, That the Council of the California Medical Association be instructed to take such necessary legal and/or legislative action to bring about protection to the doctors and hospitals of California under such circumstances.

Your committee moves the passage of this resolution.

The motion was seconded and the resolution adopted without debate.

* * *

Doctor Crosby: In regard to Resolution No. 4, which reads:

Resolution No. 4: Concerning the Use of the Name of the California Medical Association in Connection with Proposed Legislation

Resolved, By the House of Delegates, that members of the California Medical Association are instructed not to submit proposed laws to the State Legislature, using in connection therewith the name of the California Medical Association or any of the component county societies or branches, unless such proposed articles shall have received the general approval, first, of the proper component county medical society, and, in addition, the approval of the California Medical Association (through one of its constituted bodies in authority, viz., the C. M. A. House of Delegates, the Council or Executive Committee) before being passed on to the Legislative Committee of the California Medical Association for introduction to the State Legislature; and, be it further

Resolved, That when proposed laws are introduced before the California Legislature, without the above general procedure having been observed, then the C. M. A. Committee on Public Policy and Legislation shall be under no obligation to give the same its support, until, through mail or other vote of one of the properly constituted authoritative bodies of the C. M. A., it shall have first learned the wishes of the State Medical Association in regard thereto.

Again a modification of wording in amended resolution No. 4.

Resolution No. 4: Resolution on Procedure in Presenting Proposed Laws to the Legislature.

Resolved, By the House of Delegates, that members of the California Medical Association are instructed not to submit proposed laws to the State Legislature, using in connection therewith the name of the California Medical Association or any of the component county societies or branches, unless such proposed articles shall have received the general approval, first, of the proper component county medical society, and, in addition, the approval of the California Medical Association (through one of its constituted bodies in authority, viz., the House of Delegates, the Council or Executive Committee) before being passed on to the Legislative Committee of the California Medical

Association for introduction to the State Legislature; and, be it further

Resolved, That when proposed laws are introduced before the California Legislature, without the above general procedure having been observed, then the Committee on Public Policy and Legislation shall be under no obligation to give the same its support.

Mr. Chairman, we move the adoption of the modified wording of this resolution.

Motion seconded by Doctor Gibson.

Dr. Junius Harris: I move to strike out the first "California Medical Association and county societies," using the name of the State C. M. A. and county society. We do not submit these laws using the names. Please re-read.

Doctor Crosby: Resolved, by the House of Delegates, that members of the California Medical Association are instructed not to submit proposed laws to the State Legislature, using in connection therewith the name of the California Medical Association.

Doctor Harris: Now, that should be deleted.

Doctor Crosby: . . . or any of the component county societies or branches. . . .

Doctor Harris: Now, second. The rest is all right.

Doctor Crosby: . . . unless such proposed articles shall have received the general approval.

The Speaker: Will the seconder accept that amendment? He does. Is there any discussion on this? It is moved and seconded that the substitute resolution as presented by the committee be adopted. All those in favor say aye.

The amendment was accepted as read.

* * *

Doctor Crosby: Resolution No. 5.

The Anesthesiology Section of the California Medical Association respectfully submits:

Resolution No. 5: Regarding the Practice of Anesthesia as a Medical Service

Whereas, A decision of the California State Supreme Court affirmed the decision of the Superior Court in and of the County of Los Angeles that the practice of nurse anesthesia under the immediate direction and supervision of the operating surgeon is not a violation of the State Medical Practice Act; now, therefore be it

Resolved, That the House of Delegates instruct the Council to take all advisable and necessary action to protect the practice of anesthesia in California from lay invasion by technicians, and to consult with the State Board of Medical Examiners, to protect the ruling of the State Board of Medical Examiners authorized on February 27, 1928.

This resolution is modified in wording and the Anesthetic Section of the California Medical Association respectfully submits amended Resolution No. 5.

Whereas, A decision of the California State Supreme Court affirmed the decision of the Superior Court in and of the County of Los Angeles that the practice of nurse anesthesia under the immediate direction and supervision of the operating surgeon is not a violation of the State Medical Practice Act; now, therefore be it

Resolved, That the House of Delegates instruct the Council to take all advisable and necessary action to protect the practice of anesthesia in California from lay invasion by technicians.

Doctor Crosby: With this wording, the committee, Mr. Speaker, moves that the resolution pass. . . .

The Speaker: Doctor Adams seconds the substitute resolution.

Doctor Chalmers-Francis is recognized.

Doctor Chalmers-Francis: Mr. Speaker and honorable delegates of the California Medical Association: You all heard the report of the Council of the California Medical Association. It therefore is not necessary for me to remind you that the decision of the Supreme Court was based on the evidence which was produced on behalf of nurse anesthesia. The resolution I ask your permission to withdraw, because the action already taken by the Council is entirely satisfactory to the Anesthetic Section of the State of California.

The Speaker: This resolution is regularly before the House. It can be withdrawn, however, by the consent of the mover and the seconder.

The resolution was withdrawn.

Doctor Crosby: Resolution No. 6. We're getting pretty close to the end. (Applause.)

* * *

Resolution No. 6: On Malignancy in Relation to Industrial Insurance

Resolved, That the Council of the California Medical Association be instructed to institute a study of the relation between trauma and malignancy and, if deemed advisable, to initiate legislative changes in the Workmen's Compensation Law establishing a tribunal of surgeons and pathologists adequately trained and experienced in the diagnosis of malignant disease, to which all industrial cases in question shall be referred for determination as to the relationship of the trauma to the malignancy.

The passage of this we move without modification.

The motion was seconded and duly adopted.

Doctor Crosby: Resolution No. 7.

* * *

Resolution No. 7: On Practice of Medicine by Corporations

Resolved, That the Council of the California Medical Association be instructed to institute proper legal action against a member or members of the California Medical Association who are or may be aiding and abetting corporations practicing medicine in violation of existing laws.

We have seen fit to change the wording on advice. The committee does not recommend the adoption of this resolution for the following reason:

The purpose is to procure an effective court ruling against a corporation practicing medicine, and to proceed under the terms of the resolution would result, inevitably, in the injury of the member. If successful under the resolution as proposed, the State Board of Medical Examiners would have no alternative but to deprive the member involved of his license.

In failing to recommend the passage of this resolution, your committee is offering this as a substitute:

Resolved, That the Council of the California Medical Association be, and it is hereby instructed to cause such proper legal action to be instituted as shall, in its opinion, be necessary to terminate the practice of medicine by corporations contrary to law.

The motion was seconded.

The Speaker: It has been moved and seconded that the substitute resolution that you have just heard be adopted. Is there debate on it? If you gentlemen will pardon the Speaker, do you realize that this commits us to legal action? Just so that you will understand it, I will read it again.

The Speaker reread resolution.

Mr. Peart, I would like to know what that means.

Mr. Peart: Well, it means the selection of such remedies as may be available. It means court proceedings. If the Council on a survey which we would make determined to institute those proceedings, we would probably have to introduce a number of them, because it is already established in California that a corporation cannot lawfully practice medicine. It has been established in the case of the Pacific Employers' Insurance Company against the Insurance Commission. Now, just what remedies would be evoked, of course, I'd like to study. They might be criminal or they might be civil.

The Speaker: Doctor Wilson.

Doctor Wilson: Mr. Speaker, does the question refer to the legal counsel or to the Council of the C. M. A.?

The Speaker: "The Council of the California Medical Association is hereby instructed to cause proper legal action to be instituted." That is, in its discretion. " . . . as shall in its opinion be necessary to terminate the practice."

Doctor Wilson: So that the quantity and number and so on would be entirely up to the Council as conditions exist. I think that would be quite safe.

The Speaker: I just wanted the House to understand. We have gone into a good many things, causing a good deal of expense, and we should know what we are authorizing.

Doctor Wilson: Mr. Speaker: Is it mandatory that the Council begin action wherever they find such practice obtaining?

The Speaker: " . . . if, in its opinion." There is the saving clause. Doctor Crosby, read it again, please.

Doctor Crosby reread resolution.

Doctor Howson: Mr. Speaker, I should like to ask Mr. Peart, our legal counsel, if this is not mandatory.

Mr. Peart: I think it is, and that is was so intended.

Doctor Howson: You mean that the sponsors of the resolution desired that it be mandatory?

Mr. Peart: Yes.

Doctor Howson: That means then, that the Council can begin action on a great many different cases at one time, and it is not whether, in the opinion of the Council, action should be begun, but the means by which this should be accomplished.

The Speaker: Doctor Kelly.

Doctor Kelly: I am afraid of this kind of resolution. The Council has been fooling around wherever it could with the slim means available to it to start proceedings of this kind. As Mr. Peart just said, it has already been decided that the practice of medicine by corporations in the State of California is not proper, it is illegal. It means going after every corporation that we find practicing medicine at the present time, and just chasing them down, one by one, through a series of court decisions for each one, and if, in our opinion, that is the legal advice which we get on the way to do it, that resolution pins us down to going ahead and doing it. Now, $15 will be slim dues if we get to going in every county in the state, trying to close up all the hospitals that are paying a roentgenologist a salary at the present time, all of the corporations that are trying to sell life insurance, all of the industrial accident insurance people and corporations that have employees' medical services that are not quite inside of the law, and then wrestling around this hall with the county hospital initiative, and we will run a fair chance of having no money by Christmas. I think that in order to leave us a little leeway here for the next year, and save money so that it does not go out on the basis that we were told to do this by the House of Delegates, it had better be put as a discretionary phrase.

The Speaker: Doctor Crosby.

Doctor Crosby: When I was a young fellow practicing medicine, I was trying one time to modify the feeding of a little Portuguese baby, and I gave the family instructions in Portuguese, of which I could speak a little, and I told them what to do. The mother understood it and listened to it and paid attention. The father said to me, "Mr. Doc, how much it cost?" I did a little mental arithmetic, and I told him how much it would cost and he said: "But, Doc, that damn kid ain't never going to pay expenses." (Laughter.)

The Speaker: Doctor Chandler has the floor.

Doctor Chandler: The San Francisco delegation introduced that resolution by instructions of its Board of Directors with this in mind. I might say that the resolution was written before the present status of the Los Angeles anesthesia case was established. We had been informed by more than one person that certain hospital insurance service corporations are looking for a test case to take into court and have a legal opinion rendered, or a decision rendered which will establish legally what constitutes hospitalization, which most of us think would be an undesirable decision or an undesirable question to present to a court for a decision at this time. This resolution was put in with the intention that it would be mandatory upon the Council to do something that would bring about a decision on what constitutes—no—that it would make it mandatory on the Council to stop the practice of medicine by corporations when that has been already established by law, or by court action. Now, I appreciate that making it mandatory upon the Council to do something, and leaving it to their discretion as to the method they use in doing that something, will cost money and may involve a good deal of time, effort and expense. On the other hand, it was also our opinion on advice (I am not real sure now where we got the advice, but at the time, at least, we thought it was good advice), that all this legal proceeding could be brought about by the Board of Medical Examiners in prosecuting people who are illegally practicing medicine, that it would not necessarily be an expense and the direct action by the Council of the California Medical Association, but upon their request or instigation the State Board of Medical Examiners could prosecute anybody who is illegally practicing medicine. I would like to have that part cleared, if it can be cleared by Mr. Peart at the present moment; and if that is not so, I think the recommendation (I don't believe Doctor Kelly made it a motion, but if he did not I think he should), that the discretion be left to the Council should be enlarged a little bit.

The Speaker: Will Mr. Peart answer the question of Doctor Chandler?

Mr. Peart: I think the question should be answered by Doctor Molony.

Dr. Molony: Gentlemen: There has been a case before the State Board of Medical Examiners, of a physician in San Francisco, or rather a case of his license, in connection with this Pacific Health Corporation, and that has been put off from time to time until after this decision had been rendered. Without a doubt, the provision of the Medical Practice Act, which provides that aiding and abetting an unlicensed practitioner is proper subject for revocation of the license of any practitioner so engaged, should satisfactorily take care of this situation. I am sure that if the medical men who are aiding and abetting an unlicensed practitioner, (which could be, of course, a corporation), they would be subject to the revocation of their license.

The Speaker: Any further discussion?

The Speaker: Doctor Wessels.

Doctor Wessels: I move that this resolution be tabled.

Motion was seconded, and the resolution was tabled.

Doctor Crosby: Resolution No. 8.

* * *

Resolution No. 8: On the Practice of Medicine by Corporations

Whereas, It is against the law of the State of California for a corporation to practice medicine; and

Whereas, It is against the principles of ethics of the California Medical Association for a member to dispose of his professional attainments or his services to any lay body, organization or group of individuals by whatever name called or however organized; and

Whereas, It is known that many corporations are practicing medicine in this state and many members of this association are selling their services to these corporations because of circumstances beyond their individual control; now therefore be it

Resolved, That the Council of the California Medical Association be and hereby is instructed to prepare, with the help of its legal counsel, a letter setting forth the legal and ethical aspects of this situation, such letter to be sent to all corporations that are known to be practicing medicine and to all members of this Association that are known to be aiding and abetting them.

After conference with the proponents of this resolution, your committee has the following substitute resolution to offer.

Whereas, Subject to certain well-defined exceptions, it is against the law of the state of California for a corporation to practice medicine; and

Whereas, It is known that many corporations are practicing medicine in this state contrary to law and many members of this Association are selling their services to these corporations; and

Whereas, Many corporations and many members of this Association are not cognizant of the legal and ethical questions involved; now therefore be it

Resolved, That the Council of the California Medical Association be, and it is hereby instructed to prepare, with the help of its legal counsel, a letter setting forth the legal and ethical aspects of this situation, and to send such letter to any corporation known or believed to be practicing medicine contrary to law and to all members of this Association.

Mr. Speaker, your committee moves the acceptance of this amended resolution.

The resolution was adopted without debate.

* * *

Doctor Crosby: This report of the Special Committee on Maternal Welfare, created by the resolution of this House at Yosemite, was inadvertently lost in the file on Monday night, and was not read to the House by the member of the committee who was to do so.

Your Reference Committee has considered the report and its recommendations, and because it considers the matter important in view of the development of maternal and child welfare plans under the Federal Social Security Act, it requests permission to read the report, and that this House act upon it.

The Speaker: It is the unanimous consent that the resolution may be introduced at this time.

Doctor Crosby read the following report:

Report of the Committee on Maternal Welfare

The Committee on Maternal Welfare reports:

(1) Through one of the members a personal investigation of the Maternal and Child Health Service of the Social Security Act was made in Washington, D.C.

This Committee recommends:

(A) That the Association endorse the plan of the Division of Maternal and Child Hygiene of the California State Board of Health, in connection with this Act.

This endorsement is predicated upon:

(1) Any change in the state plan must be submitted to this committee before becoming effective.

(2) That a systematic and widespread educational program in obstetrical problems for the general practitioner (such program to include the subjects listed below*), be instituted at once in coöperation with the California State Board of Health.

(B) That this committee be continued and be authorized to coöperate with, the California State Board of Health, subject to the approval of the Council.

RALPH J. THOMPSON.
HANS F. SCHLUTER.
T. HENSHAW KELLY.
LYLE G. McNEILE.

May 24, 1936.

Doctor Crosby: Mr. Speaker, we move the adoption of this request.

The request was granted without discussion.

* * *

Doctor Crosby: Mr. Speaker, I move you the adoption of the report of this committee as a whole as amended.

Following the usual procedure, the motion was carried and the amended report adopted as a whole.

The Speaker: Doctor Crosby and Doctor Larson, the Speaker at this time desires to express thanks, not only for himself personally, but for the entire House, for this work that your committees have done. Yours were arduous duties. (Applause.) Any man accepting service on these committees bids good-bye to the scientific sections. I know the House agrees that these delegates have done for us a fine service.

* * *

Mr. Speaker: The chair recognizes Dr. Francis Pottenger.

Doctor Pottenger: Mr. Chairman, I would like to ask unanimous consent to introduce a resolution.

The Speaker: If there be no objection, Doctor Pottenger will have the unanimous consent to introduce a resolution.

No delegates objected.

Doctor Pottenger:

Resolution No. 9: On Tuberculin Testing of California Dairy Herds

Whereas, The dairy herds of California are the most seriously infected with tuberculosis of any state in the Union; and

Whereas, Dairy products from infected herds endanger the lives of human beings; and

Whereas, The tuberculin test is recognized by physicians and veterinarians throughout the world as being an efficient method for determining the presence of tuberculosis in man and animals; and

Whereas, The tuberculin test has proven to be harmless even when given to infants and small children; and

Whereas, There is an unwarranted and hostile opposition to such test being given to cattle by certain owners of dairy herds on the ground of its being inefficient and harmful; now be it

Resolved, That the California Medical Association deplores the action of such dairymen as being unwarranted and dangerous to the health of the people of California, and urges the health and political authorities of the state to prevent the sale of milk, cream, cheese, and all other dairy products unless the cattle from which the product comes has been tuberculin tested by the proper authorities, and all infected animals removed.

I move its adoption.

The Speaker: Doctor Geiger seconds the motion.

Doctor Geiger: I would like to speak on that for a minute, if I may.

The Speaker: You may, Doctor Geiger.

Doctor Geiger: Mr. Speaker and Members of the House: This is a very important resolution. I am sorry that it has not been brought up before. This discussion, especially as to the efficacy of the tuberculin test of cattle, has been carried on in the San Joaquin Valley to the extent that the Portuguese group have been classified as being un-American and so forth. I wish to state here, however, that in a conference with the Portuguese consul in my office in San Francisco, we came to the conclusion that he would, representing the Portuguese Government, urge the tuberculin test on all Portuguese farmers. I would like to see this resolution passed as a public health measure and, with the consent of the man who produced it, I would prefer, if you will allow me to do so, to add to that resolution the words "pasteurization of milk." We are now coming face to face with one of the most insidious nonpublic health propagandas in this state in the question of pasteurization, and I think that if those words were added to it, that is, the pasteurization of the general milk supply other than certified milk, we could settle many of the problems of public health in this state in regard to milk.

The Speaker: Will Doctor Pottenger accept that? The question is on the resolution introduced by Doctor Pottenger. Is there any further discussion? . . .

Doctor Geiger: May I again ask Doctor Pottenger whether he would allow me to put in my amendment of "pasteurization of milk?"

The Speaker: Will you come to the desk, Doctor, and make the correction?

Doctor Rosson: Mr. Chairman, Doctor Rosson of Tulare.

The Speaker: Doctor Rosson of Tulare. Just a moment, Doctor Rosson. Doctor Pottenger, will you read this resolution as amended?

Doctor Pottenger: "*Resolved,* That the pasteurization of market milk is a public health measure of first magnitude."

Doctor Eusden: Should not certified milk be excepted?

Doctor Pottenger: Certified should be excepted.

Doctor Rosson: I hate to take time at this late hour, but this is a matter of great importance to Tulare County and to San Joaquin Valley, and I think I might say that the resolution is an excellent one with one minor change. The dairymen of Tulare County, a number of them, very much opposed the testing of the herds, but they were compelled to have them tested and tuberculous cattle have been taken out of the herds and destroyed, and there are more tests to be made in the future to keep the tuberculous cattle out of the herds. A great many of the Portuguese did oppose tuberculin-testing, but most of those people are glad now that it was done, because they have a better market for their milk. In regard to the pasteurization, that will work quite a hardship upon some of the dairymen of Tulare County and the San Joaquin Valley, because of the fact that there is only one dairy, as far as I know, in my part of the state that produces certified milk. Nevertheless, I think that the pasteurization of the milk, and compelling it to be pasteurized, will be an excellent thing, and that the dairymen will eventually look upon that the same way as they look upon the destroying of the tuberculous cattle. In regard to the last couple of words in the last part of the resolution, I should think that it should read not from "tested herds," but from "infected herds," because a year or so ago (up to a year ago I believe it was) the herds in Tulare County and other places were tested, but the tuberculous cattle were not destroyed and the milk continued to be sold from tuberculous herds, so I think it would be much better to have that wording "infected herds."

18. Complications of the Neonatal Period.

Doctor Rosson: "Nontested and infected," that would seem to cover it, so that milk from infected cows could not be sold.

The Speaker: Is there any further discussion of this resolution?

Dr. Junius Harris: I would like to discuss this myself. I do not think there are enough "whereases" in Doctor Pottenger's description, and I want to add one more "whereas" to the possibility and the probability in this rather vital and important group of "whereases." You must remember that this subject has been long discussed (and I think my friend, Doctor Geiger, can remember when I was an assistant in the State Board of Health when he was there also, many years ago), and that the same problem came up in the legislative halls. The results are now showing in the State of California, by having, through the State's inaction, the greatest number of infected herds of all states in the Union. . . .

The Speaker: All those in favor of the resolution as these gentlemen have finally presented it, say "aye."

. . . The resolution was adopted as amended.

* * *

Notice of Proposed Amendment to the Constitution: On Limitation of Funds to Be Appropriated

Doctor Molony: Mr. Speaker, I ask the unanimous consent of the House to introduce notice of an amendment to the Constitution of the Association.

The Speaker: If there be no objection on the part of the House, Doctor Molony has the floor.

Doctor Molony:

Resolved, That Section 1 of Article XI of the Constitution of this Association be and it is hereby amended as follows:

By striking out all of the fourth paragraph of said Section 1 of Article XI, reading as follows:

"All resolutions providing for appropriations shall be referred to the Council, and all appropriations approved by the Council shall be included in the annual budget."

And by inserting in lieu thereof the following: "Any resolution passed and adopted by the House of Delegates at any regular or special session thereof, which provides for or contemplates the appropriation or expenditure of more than the sum of $1,000, shall not be effective for any purpose unless and until approved by the Council. All appropriations, regardless of amount, approved and made by the Council shall, if expended, be reported to the House of Delegates at its next annual session, and any unexpended portion of any thereof shall be included in the annual budget.

The Speaker: This will lie on the table until next year.

* * *

The Speaker: Gentlemen of the House: That concludes most of the business. Your Speaker has a resolution to suggest, if you have no objection:

Resolution of Appreciation

The California Medical Association, approaching the close of its Sixty-fifth Annual Session in Coronado, inspired by the appreciation, enjoyment, comfort and unbounded hospitality that have been experienced by all members in attendance, desires to give evidence of its appreciation. Therefore be it

Resolved, That the Association's secretary transmit our sincere thanks and gratitude to the following who have made most generous contributions of time, labor and friendliness to all members in attendance, and will cause us to depart to our respective homes with such pleasant memories that will endure and abide with us:

Officers and members of the San Diego County Medical Society.

Officers of the United States Naval Hospital.

Our guest speakers.

The editorial and phototorial staffs of the San Diego newspapers and news agencies.

The management and staff of the Hotel del Coronado.

The Auxiliary of the San Diego County Medical Society.

The city and county officials, and all others who have contributed to our comfort and pleasure.

The Speaker would be glad to entertain a motion that this resolution be adopted.

The motion was made by Doctor Crosby, seconded by Doctor Gibbons, and the resolution was unanimously adopted.

* * *

The Speaker: Gentlemen of the House, in bringing a last meeting of the House of Delegates to conclusion, there is always a note of regret as well as of happiness, for we part with the man who has served as our president for the year, while we turn to greet our incoming leader.

This first feeling is greatly accentuated tonight. President Peers is not with us because of the sudden critical illness today of his dearly beloved mother. We have a report late this evening that she is sinking rapidly. He has given so freely of himself in our behalf; his friendship for "his boys," as he calls us, has been so real and true that we all regret that he could not have concluded the Coronado meeting happily. The Speaker would be pleased to receive a motion authorizing the secretary to convey to Doctor Peers, on behalf of the House and the Association, a resolution of grateful appreciation for his devoted service to this Association, and of our sympathy for him in this time of sorrow.

It was moved and seconded that this resolution be adopted.

The Speaker: Now, Doctor Morrow, Mr. President-Elect, will you come to the platform? President Pallette, will you stand? It is customary to pass the badges of the president and the president-elect on to the incoming officers. The president's badge is not here. You will receive that later. Gentlemen, your new officers. (Applause.)

We will now hear from President Pallette.

Doctor Pallette: Mr. Speaker, this is Pallette of California. These days in our annual meeting are very busy ones. In fact, I have been so busy the last few days that I have forgotten a date, which no married man should ever forget, for it was only a few moments ago that I was reminded by telegram from our home town that today is Mrs. Pallette's birthday. Now I think this experience perhaps is indicative of what is going to happen to me and my family during the next year. I suspect that, at the end of this coming year, I will not only have forgotten the birthdays of my wife, children, and grandchildren, but I may have even forgotten that I have a wife or children or grandchildren! There is a lot of work ahead for all of us. Bill Toland and Bob Peers have each been declared, at the end of their year's work, among the great presidents of the California Medical Association. I think at the time those declarations were made we were right, and I think all of the twelve living past presidents will agree with that sentiment. Now, tonight, you have chosen as president-elect another prominent member of the California medical profession. It has been my privilege during the past four years to serve as a member of one of the State Board of Health, of which Dr. Howard Morrow is president. Dean Chandler has referred to the prodigious capacity and willingness of Tom Kelly as a worker in the Council, and I think we can say the same thing of Howard Morrow in the State Board of Health. Doctor Morrow has given an enormous amount of time and has shown an enormous amount of ability and judgment, and I am sure that two years from now we will be saying that Howard Morrow is also one of the greatest presidents the California Medical Association has ever had.

I have one request to make. I hope that every delegate here will go home and report to his county society and fellow members that the general officers of the State Association, the members of its Council, and Executive Committee, of the standing and special committees, are all striving to do their utmost for the welfare of scientific and organized medicine in the State of California. Thank you. (Applause.)

The Speaker: If there is no further business, we stand adjourned without day.

The meeting was adjourned at 12:15 a. m.

Attest: W. W. Roblee, *Speaker*.
F. C. Warnshuis, *Secretary*.

COUNCIL MINUTES*

Minutes of the Two Hundred and Forty-Second Meeting of the Council of the California Medical Association

Held in the Gold Room, Hotel Del Coronado, Coronado, California, Sunday, May 24, 1936, at 8 p. m.

1. **Call to Order.**—The meeting was called to order by the chairman, T. Henshaw Kelly, with the following members present: President Robert A. Peers, President-Elect Edward M. Pallette, Speaker W. W. Roblee, Chairman T. Henshaw Kelly, Councilors Morton R. Gibbons, C. O. Tanner, K. L. Schaupp, Calvert L. Emmons, Carl R. Howson, Henry J. Ullmann, A. E. Anderson, Alfred L. Phillips, O. D. Hamlin, C. E. Schoff, Henry S. Rogers, William H. Kiger, J. B. Harris; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart.

2. **Report of Council.**—T. Henshaw Kelly, chairman, presented the annual report of the Council, which was discussed section by section and certain additions recommended, approval of the report being deferred until the Monday meeting of the Council.

3. **Report of the Committee on Scientific Sections.**—Morton R. Gibbons, chairman of the Committee on Revision of Scientific Sections, submitted a report on plans for elimination of the multiplicity of section meetings at annual sessions.

Councilor Morton R. Gibbons moved, seconded by Councilor Kiger, that the sections be consulted and given an opportunity to study the problem and that the Council be authorized to make the necessary changes in system when and if a satisfactory plan is devised. Carried.

4. **Committee on Malpractice Insurance.**—George G. Reinle, chairman of the Committee on Malpractice Insurance, submitted a written report recommending that the Association do not enter into the insurance business at this time, since satisfactory coverage can be secured by members from commercial insurance carriers.

It was moved by Councilor Wilson, seconded by Councilor Ullmann, that the report of the Committee on Malpractice Insurance be accepted and approved by the Council and that it be submitted to the House of Delegates with the Council's annual report. Carried.

5. **Committee on Tax-Supported Hospitals and Medical Care.**—A. E. Anderson, chairman of the Committee on Tax-Supported Hospitals, submitted a supplemental report to the report of the Committee as published in the Pre-Convention Bulletin.

It was moved by Councilor Rogers, seconded by Councilor Ullmann, that the report be accepted. Carried.

It was moved by President Peers, seconded by Councilor Anderson, that Mr. Alfred Siemon be invited to address the House of Delegates on Monday evening. Carried.

After discussion of the value of the tax cartoons published by the State Chamber of Commerce, on motion of Editor Kress, seconded by President-Elect Pallette, the secretary and the editor were empowered to insert reprints of these cartoons in the Journal as a supplement at a cost not in excess of $500. Carried.

It was moved by Councilor Wilson, seconded by Speaker Roblee, that the county hospital matter be given preference and first consideration by the House of Delegates and the Council, and that the committee be continued, to work through the Council and the Committee on Public Policy and Legislation. Carried.

---

* The minutes of the two hundred and forty-first meeting of the Council of the California Medical Association were printed in the May, 1936, issue of California and Western Medicine, page 437.

6. **Committee on Disciplinary Procedures.**—Speaker Roblee, chairman of the Committee on Disciplinary Procedures, outlined proposed amendments to his report as published in the Pre-Convention Bulletin and, with the approval of the Council, consideration of the report was deferred until Monday's Council meeting.

7. **House of Delegates Order of Business.**—In accordance with constitutional provision, the order of business of the two meetings of the House of Delegates were approved.

8. **Reports of Standing Committees.**—After consideration, on motion of Editor Kress, seconded by Councilor Kiger, the reports of Standing and Special Committees, as published in the Pre-Convention Bulletin; were approved for transmission to the House of Delegates.

9. **Annual Dues.**—It was moved by President Peers, seconded by Councilor Ullmann, and Councilor Gibbons, that the Council recommend to the House of Delegates that the House of Delegates make the dues of the California Medical Association for the year 1937 at $15 for that year. Carried.

10. **Standing Committee Memberships.**—It was moved by Councilor Gibbons, seconded by President-Elect Pallette that the chairman appoint a committee of three to review the membership of Standing Committees. Carried.

The chairman appointed Doctors Kiger, Schaupp, and Schoff.

11. **Adjournment.** — At this point, 11:45 p. m., the Council adjourned to meet at 2 p. m. Monday.

T. Henshaw Kelly, *Chairman.*
F. C. Warnshuis, *Secretary.*

* * *

Minutes of the Two Hundred and Forty-Third Meeting of the Council of the California Medical Association

Held in the Gold Room, Hotel Del Coronado, Coronado, California, Monday, May 25, 1936, at 2 p. m.

1. **Call to Order.**—The meeting was called to order by the chairman, T. Henshaw Kelly, with the following members present: President Robert A. Peers, President-Elect Edward M. Pallette, Speaker W. W. Roblee, Chairman T. Henshaw Kelly, Councilors Morton R. Gibbons, C. O. Tanner, Karl L. Schaupp, Calvert L. Emmons, Carl R. Howson, H. J. Ullmann, A. E. Anderson, Alfred L. Phillips, O. D. Hamlin, C. E. Schoff, Henry S. Rogers, William H. Kiger, J. B. Harris; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart.

Absent: None.

2. **Medical Society of the State of California.**—At this point a recess of the Council was declared to permit a meeting of the Medical Society of the State of California.

3. **Report of Council.** — The Council was called to order after the recess, and consideration was given to the report of the Council.*

It was moved by Editor Kress, seconded by President Peers, that a short statement be included in the Council's report imparting the relationship of the Medical Society of the State of California and a brief outline of cases settled, pending and dismissed. Carried.

It was moved by President Peers, seconded by Chairman of Public Relations Committee Dukes, that the editor include in some issue of the Journal an historical article on the Indemnity Defense Fund. Carried.

It was moved by Speaker Roblee, seconded by Councilor Ullmann, that the report of the Council, as amended, be approved for submission to the House of Delegates. Carried.

4. **Code for Disciplinary Procedure.**—Speaker Roblee, chairman of the Committee on Disciplinary Procedure, presented his report, which was discussed in detail.

It was moved by Councilor Ullmann, seconded by President-Elect Pallette, that the report of the committee be approved for submission to the House of Delegates. Carried.

5. **Adjournment.**—It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Rogers, that the Council adjourn to meet at 9 a. m. Tuesday.

T. Henshaw Kelly, *Chairman.*
F. C. Warnshuis, *Secretary.*

* * *

Minutes of the Two Hundred and Forty-Fourth Meeting of the Council of the California Medical Association

Held in the Gold Room, Hotel Del Coronado, Coronado, California, Tuesday, May 26, 1936, at 9 a. m.

1. **Call to Order.**—The meeting was called to order by Chairman T. Henshaw Kelly, with the following members present: President Robert A. Peers, President-Elect Edward M. Pallette, Speaker William W. Roblee; Chairman T. Henshaw Kelly, Councilors C. O. Tanner, Karl L. Schaupp, Calvert L. Emmons, Carl R. Howson, Henry J. Ullmann, A. E. Anderson, Alfred L. Phillips, C. E. Schoff, Henry S. Rogers, William H. Kiger, J. B. Harris; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart.

Absent: Councilors Hamlin and Gibbons.

2. **Appeals.**—It was moved by Councilor Harris, seconded by Councilor Ullmann, that the Council convene in executive session at 2 p. m. Wednesday, May 27, 1936, for consideration of the appeals which are at present before it. Carried.

3. **Reinstatement of Members.** — It was moved by Councilor Ullmann, seconded by Councilor Rogers, that all members whose memberships had lapsed on account of nonpayment of dues and whose dues had been remitted since April 1 by the component county societies be reinstated to membership. Carried.

4. **Financial Statement.**—It was moved by Councilor Emmons, seconded by Councilor Ullmann, that the financial statements for the months of March and April, 1936, as mailed to all members of the Council, be approved. Carried.

5. **California Code Commission.**—It was moved by President Peers, seconded by Councilor Schaupp, that the matter of the proposed business and professional code of the California Code Commission be referred to the chairman of the Committee on Public Policy and Legislation and the General Counsel. Carried.

6. **Bureau of Registration of Nurses.**—It was moved by Chairman of Public Relations Committee Dukes, seconded by President Peers, that Benjamin Black be appointed as the Association's northern representative on the Bureau of Registration of Nurses' Advisory Committee. Carried.

7. **Dues.**—It was moved by President Peers, seconded by Councilor Harris, that where a request is made for a refund of dues of a deceased member such refund be made in proportion to the unexpired time. Carried.

8. **Medical Practice Act.**—The secretary read a proposed amendment to the Medical Practice Act, Section 14 (12-a), suggested by the San Diego County Medical Society, providing that "advertising definite or fixed prices for professional services" be included as a cause for revocation of license.

It was moved by Councilor Kiger, seconded by Editor Kress, that the proposed amendment be referred to the chairman of the Legislative Committee and the General Counsel. Carried.

9. **County Society Organizations.**—The secretary presented a report on the organization of county societies in California.

---

* For report of the Council, see minutes of the House of Delegates, which appear on page 71.

It was moved by Editor Kress, seconded by President Peers, that the secretary write to the American Medical Association calling its attention to the dual set-up of certain county societies and requesting that the proper footnote be included in any further reports on county organizations in California. Carried.

10. **Council Report.**—It was moved by Councilor Howson, seconded by Councilor Schaup, that mimeographed copies of the report of the Council be presented to members of the House of Delegates. Carried.

11. **Forestry Reserves.**—It was moved by Councilor Ullmann, seconded by Councilor Rogers, that Doctors Harris and Warnshuis and Mr. Peart be authorized to take the necessary steps with the State Chamber of Commerce to perfect the reorganization of the State Forestry Reserves. Carried.

12. **Retired Membership.**—It was moved by Councilor Ullmann, seconded by Councilor Harris, that Henry Lewis Wagner, member of the San Francisco County Medical Society, be granted retired membership in the California Medical Association. Carried.

13. **California Drugless Physicians, Inc.** — It was moved by Councilor Rogers, seconded by Councilor Ullmann, that the correspondence from the California Drugless Physicians be referred to the Legislative Committee and the General Counsel. Carried.

14. **Constitution and By-Laws.** — It was moved by Speaker Roblee, seconded by Councilor Harris, that the secretary and the editor be authorized to print the Constitution and By-Laws in CALIFORNIA AND WESTERN MEDICINE in a separate and extra form and that sufficient reprints be made to have copies available for members. Carried.

15. **American Medical Association.** — A letter was read from the San Francisco County Medical Society suggesting that the American Medical Association be invited to hold its annual meeting in California during 1938.

It was moved by Editor Kress, seconded by Councilor Kiger, that the California Medical Association give its approval to the invitation to the American Medical Association to hold its 1938 meeting in San Francisco and that the secretary transmit the invitation to the secretary of the American Medical Association. Carried.

16. **Correspondence.**—Correspondence from a member of the San Francisco County Medical Society regarding an article which appeared in the San Francisco County Bulletin, was read.

It was moved by Councilor Ullmann, seconded by Councilor Rogers, that a letter be sent to Doctor Brown calling attention to the fact that the article in question appeared in the San Francisco County Bulletin and that correspondence regarding it should, therefore, be addressed to the county society. Carried.

17. **Nevada State Society.**—A letter from Secretary Brown of the Nevada State Medical Association concerning certain papers which had been read before the Nevada Association and submitted to CALIFORNIA AND WESTERN MEDICINE for publication, but which it was not possible to accept, was read and discussed. The heavy demands on the space of CALIFORNIA AND WESTERN MEDICINE by members of the California Medical Association, and the fact that practically one-half or more of all California Medical Association annual session papers must be declined on that account, made necessary a reconsideration of the agreement with the Nevada Medical Association of several years ago, in regard to publication of that Association's annual session papers. It was pointed out that a limited number (about eighty) of the Nevada State Association members were given a special two-dollar subscription rate, although members of the California Medical Association were themselves assessed on a three-dollar subscription basis. It was felt that, as an expression of fraternal courtesy, this rate for Nevada Association members whose subscriptions were sent through the office of the secretary of the Nevada State Medical Association should continue, but that under existing circumstances and the heavy space demands by California Medical Association members it would be necessary to terminate the old understanding and arrangements concerning CALIFORNIA AND WESTERN MEDICINE. Upon motion duly made and seconded, it was so ordered.

It was also voted that a courteous letter of explanation of the above action be sent to the Nevada State Medical Association.

18. **California and Western Medicine.**—It was moved by Councilor Ullmann, seconded by Councilor Rogers, that the editor be authorized to increase the JOURNAL sixteen pages until the present overflow of accepted papers is published. Carried.

19. **Association of California Hospitals.**—Resolution of the Association of California Hospitals on maternity hospitals was ordered filed since the matter is covered by law.

20. **Adjournment.** — At this point the Council adjourned to meet at 2 p. m. Wednesday, May 29, 1936.

T. HENSHAW KELLY, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

* * *

Minutes of the Two Hundred and Forty-Fifth Meeting of the Council of the California Medical Association

Held in the Gold Room, Hotel Del Coronado, Coronado, California, Wednesday, May 27, 1936, at 2 p. m.

1. **Call to Order.**—The meeting was called to order by Chairman T. Henshaw Kelly, with the following members present: President Robert A. Peers, President-Elect Edward M. Pallette, Speaker William W. Roblee, Chairman T. Henshaw Kelly, Councilors C. O. Tanner, Karl L. Schaupp, Calvert L. Emmons, C. R. Howson, Henry J. Ullmann, A. E. Anderson, A. L. Phillips, O. D. Hamlin, Morton R. Gibbons, C. E. Schoff, Henry S. Rogers, W. H. Kiger, J. B. Harris; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress; Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart.

2. **Scientific Contributions.** — A request for Council action on the matter of ownership and publication of scientific papers was received.

It was moved by Editor Kress, seconded by Councilor Ullmann, that inasmuch as papers read in the scientific sections are original contributions that have not been previously read or presented before similar organizations, it be

Resolved, That the rule be established for the guidance of section officers when confronted with a scientific paper which the author has previously presented or published elsewhere, as follows: That section officers, under this rule, be instructed to decline to permit the author to read such a paper before any section during an annual session, and refer the matter to the Executive Committee of the Council. This rule is to be interpreted that it does not apply to members who have presented and worked up their symposium or paper before a group of specialists or in various intercounty physicians' meetings of special organizations.

3. **Annual Session of 1937.**—Dr. Mast Wolfson extended the invitation of the Monterey County Society for the holding of the next annual session in Del Monte.

Invitation from the Sacramento Society to hold the annual session at Sacramento was read and the facilities in Sacramento presented by Mr. Roy Clare.

It was moved by Chairman of Public Relations Dukes, seconded by President-Elect Pallette, that the 1937 annual session be held at Del Monte. Carried. Doctors Schoff and Harris voted in the negative.

It was moved by Councilor Ullmann, seconded by Councilor Wilson that the Executive Committee be empowered to set the date of the next annual session. Carried.

4. **Invited Guests.**—It was moved by Councilor Wilson, seconded by Councilor Emmons, that the expenses of invited guests be left to the Auditing Committee. Carried.

5. **Standing Committees.**—William H. Kiger, chairman of the committee appointed to review the membership of Standing Committees, presented the committee's recommendations, which were approved by the Council for submission to the House of Delegates. (See minutes of House of Delegates for membership of committees.)

6. **Cancer Commission.**—In accordance with constitutional provision, President-Elect Pallette reported that he had reappointed as members of the Cancer Commission Henry J. Ullmann, Clarence G. Toland, and Harold Brunn. The appointments were approved by the Council for submission to the House of Delegates.

7. **Expert Testimony.**—A case involving a policy of remuneration of physicians for the furnishing of testimony in court was brought to the attention of the Council.

It was moved by Councilor Ullmann, seconded by Chairman of Public Relations Committee Dukes, that the general counsel be empowered to act in the case; legal expense not to exceed $300, and printing and court costs not to exceed $450. Carried.

Kern County Appeal. — (*a*) Roll call recorded all councilors present. President-Elect Pallette and Councilor Tanner not having heard all the arguments did not participate in the deliberations or the decision.

(*b*) The secretary certified that all briefs and arguments had been supplied to each voting member of the Council.

(*c*) The Council then considered and discussed all the documents comprising the record, including the transcript of the proceedings, and discussed and deliberated upon and considered the same and the oral arguments and the written arguments in the matter of each of said appeals.

(*d*) The following motion was made by Councilor Rogers, seconded by Councilor Wilson:

Resolved, That the Council of the California Medical Association approve and affirm the action of the Kern County Medical Society and its Board of Directors in the disciplinary proceedings taken against Dr. Joe Smith, resulting in his expulsion from said society on November 25, 1935, and that this resolution shall be and constitute the decision of the Council of this Association on the appeal of said Dr. Joe Smith.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Rogers, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association modify the action of the Board of Directors of the Kern County Medical Society in the disciplinary proceedings taken against John M. Kirby, resulting in his suspension from said society on November 25, 1935, for a period of fifteen years, by reducing said period of suspension to the period of one year and that in all other respects said action shall be and is hereby approved and confirmed and that this resolution shall constitute the decision of the Council of this Association on the appeal of said Dr. John M. Kirby.

Said resolution was carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schaupp, seconded by Councilor Anderson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association modify the action of the Board of Directors of the Kern County Medical Society in the disciplinary proceedings taken against R. M. Jones, resulting in his suspension from said society on November 25, 1935, for a period of fifteen years, by reducing said period of suspension to the period of one year and that in all other respects said action shall be and is hereby approved and confirmed and that this resolution shall constitute the decision of the Council of this Association on the appeal of said Dr. R. M. Jones.

Said resolution was carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Rogers, seconded by Councilor Schoff, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association modify the action of the Board of Directors of the Kern County Medical Society in the disciplinary proceedings taken against Homer Rogers, resulting in his suspension from said society on November 25, 1935, for a period of five years, by reducing said period of suspension to the period of one year and that in all other respects said action shall be and is hereby approved and confirmed and that this resolution shall constitute the decision of the Council of this Association on the appeal of said Dr. Homer Rogers.

Said resolution was carried by the affirmative votes of all of the councilors present and acting.

San Francisco County Society Appeals.—(a) Roll call recorded all participating councilors and officers present. Councilors Gibbons and Schaupp, being ineligible to participate, withdrew and left the executive session.

(*b*) The secretary certified that all briefs had been supplied to each voting member of the Council.

(*c*) On inquiry by the chairman, all voting members of the Council affirmed that they had read all of the briefs of the appellants and respondents.

(*d*) The Council then considered and discussed all the documents comprising the record, including the transcript of the proceedings, and discussed and deliberated upon and considered the same and the oral arguments and the written arguments in the matter of each of said appeals.

(*e*) The following motion was made by Councilor Ullmann, seconded by Councilor Rogers:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken on February 17, 1936, against F. W. Callison, resulting in his expulsion from said society, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said F. W. Callison.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Bertram Stone, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Bertram Stone.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Frank E. Stiles, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Frank E. Stiles.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Edward M. Talbott, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Edward M. Talbott.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against James F. Pressley, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said James F. Pressley.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Louis Clive Jacobs, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Louis Clive Jacobs.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against George J. Heppner, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said George G. Heppner.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Harry W. Davis, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Harry W. Davis.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Herbert J. Cohn, resulting in his suspension from said society for a period of ninety days, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Herbert J. Cohn.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

* * *

On motion of Councilor Schoff, seconded by Councilor Wilson, and unanimously carried, the following resolution was adopted:

Resolved, That the Council of the California Medical Association approve and affirm the action of the San Francisco County Medical Society and its Board of Directors in the disciplinary proceedings taken February 17, 1936, against Joy L. McClure, resulting in his suspension from said society for a period of one year, and that this resolution shall be and constitutes the decision of the Council of this Association on the appeal of said Joy L. McClure.

A vote was then taken on said motion and said motion was unanimously carried by the affirmative votes of all of the councilors present and acting.

The Council arose from executive session and instructed the secretary to notify all parties concerned as to the action recorded by the Council.

9. **Administration of Anesthetics.**—It was moved by Councilor Rogers, seconded by Councilor Schaupp, that Mr. Peart be instructed to ask for a new hearing in the case of *Francis* vs. *Nelson*. Carried.

10. **Adjournment.**—On motion of Councilor Ullmann, seconded by Speaker Roblee, the Council adjourned to meet at 9 a. m. Thursday, May 28, 1936.

T. Henshaw Kelly, *Chairman*.
F. C. Warnshuis, *Secretary*.

* * *

Minutes of the Two Hundred and Forty-Sixth Meeting of the Council of the California Medical Association

Held in the Gold Room, Hotel Del Coronado, Coronado, California, Thursday, May 28, 1936, at 9:30 a. m.

1. **Call to Order.**—The meeting was called to order by the chairman *pro tem*, with the following members present: President Edward M. Pallette, President-Elect Howard Morrow; Speaker William W. Roblee; Councilors T. Henshaw Kelly, Morton R. Gibbons, C. O. Tanner, Karl L. Schaupp, Calvert L. Emmons, Carl R. Howson, Henry J. Ullmann, A. E. Anderson, Alfred L. Phillips, O. D. Hamlin, C. E. Schoff, Henry S. Rogers, William H. Kiger, J. B. Harris, H. Wilson; Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart. (Past President Peers was absent on account of the serious illness of his mother.)

2. **Chairman of Public Relations Committee.**—The secretary announced that the committee had elected Charles A. Dukes, chairman, and that Doctor Dukes was, therefore, a member of the Council.

3. **Chairman of Council.**—On nomination of Councilor Kelly, seconded by Councilor Kiger, Morton R. Gibbons was unanimously elected chairman of the Council for the ensuing year. Doctor Gibbons was inducted as chairman and assumed the chair.

4. **Vice-Chairman of Council.** — On nomination of President Pallette, seconded by Councilor Hamlin, Junius B. Harris was unanimously elected vice-chairman of the Council for the ensuing year.

5. **Secretary-Treasurer.**—On nomination of Councilor Howson, seconded by Councilor Hamlin, Frederick C. Warnshuis was unanimously elected secretary-treasurer of the Association for the ensuing year.

6. **Editor.**—On nomination of Chairman of Public Relations Committee Dukes, George H. Kress was unanimously elected editor of CALIFORNIA AND WESTERN MEDICINE.

7. **General Counsel.** — It was moved by Councilor Rogers, seconded by Speaker Roblee, and unanimously carried, that Hartley F. Peart be appointed general counsel for the California Medical Association.

8. **Associate General Counsel.** — It was moved by Councilor Rogers, seconded by Councilor Ullmann, and unanimously carried, that Hubert T. Morrow be appointed associate counsel for the California Medical Association without retainer fee.

9. **Council Meeting.**—The Council delegated to the Executive Committee the power to set the date of the next meeting of the Council, so that full consideration could be given to the matter of the county hospital initiative.

10. **Salaries and Office Activities and Personnel.**—At this point the Council went into executive session, all employees of the Association absenting themselves.

After discussion, on motion of Councilor Kiger, seconded by Speaker Roblee, and unanimously carried, the salary of the secretary-treasurer and director of the Department of Public Relations was approved in accordance with the budget approved by the House of Delegates.

It was pointed out that in years past a committee had been appointed to survey the activities and expenses of the Association and the JOURNAL and that such procedure was highly desirable from the standpoint of informing the members of the Association of the details connected with the organization and finances of the Association.

It was moved by Councilor Kelly, seconded by Speaker Roblee, that a committee of three members of the Council be appointed by the chairman to prepare a plan to govern legal services rendered to the Association and that in the meantime it be understood that the general counsel, Mr. Peart, be continued in that capacity under the present retainer until the committee has submitted its report to the Council; and that the committee be also instructed to bring in a report and recommendations on other major activities and expenses of the Association for the guidance of the Council.

It was understood that the information obtained in the report be placed in such form as will be suitable for presentation to county societies for the information of all members.

It was moved by Councilor Ullmann, seconded by Councilor Rogers, that the salary of the general counsel and the editor be continued as at present until the report of the committee is received and acted upon. Carried.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Kiger, that the secretary-treasurer be empowered and given authority to direct the personnel and supervise the administrative work in the secretary-treasurer's office, and that he have the authority to engage and discharge clerical assistants of the secretary-treasurer, under budget provisions. Carried.

12. **Auditing Committee.**—Chairman Gibbons appointed as members of the Auditing Committee, Karl L. Schaupp (chairman), O. D. Hamlin, and T. Henshaw Kelly. The appointments were approved by the Council.

13. **Adjournment.**—There being no further business the Council adjourned.

MORTON R. GIBBONS, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

STATE AND COUNTY SOCIETY ACTIVITIES

TELETYPE

On June 15 a three-way teletype installation was made in the Association offices. One station is in the Association headquarters, the second in Sacramento in Dr. J. B. Harris' office, and the third in the Los Angeles County Medical Association building. This system of communication will produce the following advantages: Immediate contacts in sending and receiving messages, speed, prompt action, and reduction of telephone and telegraph bills.

Members in Los Angeles or Sacramento can immediately contact headquarters by telephoning to the Los Angeles County Medical Association executive offices or to Dr. J. B. Harris and have their messages transmitted and obtain immediate answer. The code call numbers are: California Medical Association, San Francisco, S. F. 49; Los Angeles County Medical Association, * ; Dr. J. B. Harris, Sac. 66.

* * *

COPYRIGHT

As the Editor has previously commented, each issue of CALIFORNIA AND WESTERN MEDICINE is copyrighted. Under federal copyright laws no article or portion of an article or any other printed items in any issue can be produced in any other publication without permission. The Council has delegated to Editor Kress and the secretary authority to grant requests to reprint published material. A blank permission is given to all state journals and to the *Journal of the American Medical Association.* All other publications must submit applications requesting permission to reprint articles and items.

The underlying reason is as follows: There are many medical publications that are produced for the profit obtained from adavertising. They accept any and all types of advertising down to the rankest nostrums. No reputable doctor will submit original articles to these quasi-medical journals. Their management is dependent upon reputable journals for their medical articles. These are "lifted" bodily or are abstracted and are used to fill their reading pages.

We can well do without these undesirable publications. If all state journals would pursue the same policy, these third- and fourth-grade medical catalogues would disappear. State associations will do well to enforce their copyright protection.

* * *

AMERICAN MEDICAL ASSOCIATION POLICIES

The following important policies were established by the American Medical Association House of Delegates at Kansas City.

Hospital Staffs.—Hospitals approved for intern training must have staffs composed of members of county societies.

Medical Colleges.—Urged to give a course in medical economics.

Technicians and Medical Helpers.—These to be under the supervision and absolute control of the medical profession.

Radiology.—Is the practice of medicine, and that all services connected with the practice of radiology shall be under the control of the medical profession and this same principle pertains to other professional and technical services.

Hospital Practice.—Invasion by hospitals of the field of the practice of medicine should be condemned as a violation of the fundamental rights of physicians and that it demands militant opposition to the end that such activities cease.

Hospitals.—Approval will be withdrawn from any hospitals which grant special privileges to staff members in the form of lower rates to patients.

Contraceptive Practice.—Committee continued for further study. No conclusions advanced.

Disciplination of Members.—The Judicial Council was given authority to initiate disciplinary procedures against members when county and state organizations fail to exercise disciplinary powers.

Disapproved Listing in Special Medical Directories.—It was declared to be unethical for members to pay for the listing of their names in special medical directories.

The foregoing are but a few of the more important actions of the American Medical Association. Members should read the entire minutes as published in the May 23 and May 30 issues of the *Journal of the American Medical Association.*

* * *

INDUCTION OF NEW MEMBERS

In order to become a member of a county medical organization a physician fills out an application for membership, setting forth his qualifications. These are passed upon and in due time his name is presented to the society for election. When elected he is notified and, without further ceremony, he becomes a member. This method is open to criticism and should be improved.

An individual affiliating with other organizations, his church, lodge, club, luncheon club, is received as a member with some degree of ceremony, conducted for the purposes of impressing the candidate with the purposes and policies as well as the value of membership in the organization he is joining. This is proper and meritable.

We have frequently stated that, next to his degree and license to practice, a physician's most valuable asset is his membership certificate of his county society. We admit him to membership without initiation exercises.

---

* At the time of this writing, the Los Angeles station had not been given a code number. It will be printed in a later issue.

Often the new member has never read the constitution and by-laws of his county and state medical bodies. Frequently he is without knowledge of the Principles of Medical Ethics. He does not possess this information because no one has ever given him these documents.

Therefore we suggest the following procedure. At the first meeting after which a physician has been elected to membership he should be notified to be present. At a proper time during the meeting the new member should be called to the rostrum and be greeted by the president. In his greeting the president should outline the policies and purposes of the society, relate the value, obligations and duties of membership, and welcome the new member. In conclusion, the new member should be presented with a copy of the constitution and by-laws of his county and state association and of the Principles of Ethics.

We feel that such a ceremony will be helpful and beneficial not only to the new member, but also to the older member in reminding them of their obligations. May we hear that county presidents are adopting these suggestions?

* * *

THINGS WORTH KNOWING

1. Lists of officers, councilors, committees and county societies, with names of presidents and secretaries, appear in the front advertising section of each issue of this publication.
2. Our advertisers are all approved business organizations.
3. Books and articles in California medical libraries and in the Surgeon-General's library may be obtained through your local public library.
4. Packages of recent literature may be obtained on any medical subject by writing to the Packet Library, American Medical Association, 535 North Dearborn Street, Chicago. A nominal charge of 25 cents for postage is made.
5. The American Medical Association Medical Directory lists all licensed physicians by states and counties.
6. X-ray films are the property of the radiologist.
7. Under Editorials, Association activities, and in the Department of Public Relations, members will find progress reports of all Association activities.
8. The invasion by hospitals of the practice of medicine was condemned at the recent American Medical Association meeting.
9. The American Medical Association has declared that technical services in laboratories are medical services and hence should be under medical control, and not under hospital or lay control.
10. Medical services cannot be divided into professional and technical services, is the declaration of the American Medical Association.
11. It is unethical to pay to have one's name listed in special medical directories whose publishers claim that such listings are used by insurance companies in referring patients. The Judicial Council has declared this to be the solicitation of patients. Further, that it is a racket and a "come on" game at the expense of doctors.
12. Do not sign a contract until you are informed as to its legal provisions and your legal obligations.

* * *

COMMITTEE APPOINTMENTS

Membership on special and standing committees of the Association are designated by the Council and confirmed by the House of Delegates. In this, as in every issue of our official journal, members will find the personnel of all committees listed in the front advertising section. Consult that listing and become informed as to who are obligating themselves to render special service to all our members.

Assignments to and acceptance of committee membership is not an idle honor. It is a definite obligation and pledge to contribute thought, time, and labor to accomplish that for which the committee was created and aid in accomplishing Association purposes and functions. Committees function in behalf of membership and public interests. Committees are entitled to the support and assistance of all members. Committees lead by formulating recommendations and policies. Committee accomplishments are accentuated and achieved in the fullest degree when all members enroll their support.

We confidently look forward to a year of desired action on the part of all committees.

* * *

SIXTY-FIFTH ANNUAL SESSION

Our Association's history has been enriched by the transactions and events of our sixty-fifth annual session that was held in Coronado on May 25-28, 1936. The registration was 1,594, and would have reached the 2,000 mark had everyone in attendance registered.

Coronado and San Diego have bequeathed to our members many happy memories of former meetings. This bequest has been enriched by that pleasant environment, a hospitable local profession, and a hotel management alert to our needs and comforts.

This issue contains the official minutes. Every member *is urged to read the official transactions,* to study them and to conform to the policies established. This comment will be confined to certain general details. It is not intended to supplant the reading of the official minutes.

Conference.—By Council action all of the standing and special committees met in general conference on Sunday afternoon. Association activities and future problems were presented. The conference concluded with the chairmen holding meetings of their respective committees. This innovation will go far in intensifying committee activity and accomplishments.

County presidents and secretaries joined the Council at luncheon on Tuesday for informal exchange of experiences. It was determined to hold the annual secretaries' conference in late November, after the election and before the legislature convenes.

Council.—The Council held five meetings. Its minutes are contained in this issue. At the Thursday Council reorganization meeting, the following officers were elected: Morton R. Gibbons, chairman; Junius B. Harris, vice-chairman; Karl L. Schaupp, chairman of Auditing Committee; F. C. Warnshuis, secretary-treasurer; Hartley F. Peart, legal counsel; Hubert T. Morrow, associate legal counsel; and George H. Kress, editor. Chairman Gibbons appointed the following Auditing Committee: Karl L. Schaupp, O. D. Hamlin, and T. Henshaw Kelly.

1937 Meeting Place.—The Council recommended, and the delegates approved, Del Monte as the place for holding our 1937 meeting. The exact date will be determined at the next Council meeting.

Scientific Program and Exhibits.—The members are referred to the minutes, which contain the recommendations of this committee.

Malpractice Insurance.—The complete report of this committee is to be found in the minutes together with the action of the House of Delegates.

House of Delegates.—The presiding ability of the Speaker, W. W. Roblee, and the excellent work of the two reference committees expedited the work of the House of Delegates. Delegates were well informed upon reports and pending questions. This fact obviated long explanatory statements and debate. Informed conscientious delegates are able to record sound action and policies. Speaker Roblee and Vice-Speaker Graves were reëlected to office. Councilors Phillips, Howson, Schoff, Tanner, and Kelly were reëlected. Dr. Howard A. Morrow was elected president-elect without contest.

Those in attendance were loath to depart homeward, for the comment, "The best meeting in twenty-five years," was a general expression. We shall soon return to Coronado for our annual meeting.

* * *

PRINCIPLES OF ETHICS

Article IV is an important section of our Principles of Ethics. Observing it will prevent misunderstandings.

Article IV. Duties of Physicians in Cases of Interference

CRITICISM TO BE AVOIDED

Section 1. The physician, in his intercourse with a patient under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder; nor should the course of conduct of the physician, directly or indirectly, tend to diminish the trust reposed in the attending physician. In embarrassing situations, or wherever there may seem to be a possibility of misunderstanding with a colleague, the physician should always seek a personal interview with his fellow.

SOCIAL CALLS ON PATIENT OF ANOTHER PHYSICIAN

Sec. 2. A physician should avoid making social calls on those who are under the professional care of other physicians without the knowledge and consent of the attendant. Should such a friendly visit be made, there should be no inquiry relative to the nature of the disease or comment upon the treatment of the case, but the conversation should be on subjects other than the physical condition of the patient.

SERVICES TO PATIENT OF ANOTHER PHYSICIAN

Sec. 3. A physician should never take charge of or prescribe for a patient who is under the care of another physician, except in an emergency, until after the other physician has relinquished the case or has been properly dismissed.

CRITICISM TO BE AVOIDED

Sec. 4. When a physician does succeed another physician in the charge of a case, he should not make comments on or insinuations regarding the practice of the one who preceded him. Such comments or insinuations tend to lower the esteem of the patient for the medical profession and so react against the critic.

EMERGENCY CASES

Sec. 5. When a physician is called in an emergency and finds that he has been sent for because the family attendant is not at hand, or when a physician is asked to see another physician's patient because of an aggravation of the disease, he should provide only for the patient's immediate need and should withdraw from the case on the arrival of the family physician after he has reported the condition found and the treatment administered.

WHEN SEVERAL PHYSICIANS ARE SUMMONED

Sec. 6. When several physicians have been summoned in a case of sudden illness or of accident, the first to arrive should be considered the physician in charge. However, as soon as the exigencies of the case permit, or on the arrival of the acknowledged family attendant or the physician the patient desires to serve him, the first physician should withdraw in favor of the chosen attendant; should the patient or his family wish some one other than the physician known to be the family physician to take charge of the case the patient should advise the family physician of his desire. When, because of sudden illness or accident, a patient is taken to a hospital, the patient should be returned to the care of his known family physician as soon as the condition of the patient and the circumstances of the case warrant this transfer.

A COLLEAGUE'S PATIENT

Sec. 7. When a physician is requested by a colleague to care for a patient during his temporary absence, or when, because of an emergency, he is asked to see a patient of a colleague, the physician should treat the patient in the same manner and with the same delicacy as he would have one of his own patients cared for under similar circumstances. The patient should be returned to the care of the attending physician as soon as possible.

RELINQUISHING PATIENT TO REGULAR ATTENDANT

Sec. 8. When a physician is called to the patient of another physician during the enforced absence of that physician, the patient should be relinquished on the return of the latter.

SUBSTITUTING IN OBSTETRIC WORK

Sec. 9. When a physician attends a woman in labor in the absence of another who has been engaged to attend, such physician should resign the patient to the one first engaged, upon his arrival; the physician is entitled to compensation for the professional services he may have rendered.

Article V. Differences Between Physicians

ARBITRATION

Section 1. Whenever there arises between physicians a grave difference of opinion which cannot be promptly adjusted, the dispute should be referred for arbitration to a committee of impartial physicians, preferably the Board of Censors of a component county society of the American Medical Association.

SUGGESTIONS REQUESTED

The conducting of an annual meeting demands personal attention to many details. There is but one uppermost thought—to meet, in so far as possible, the comfort and pleasure of those in attendance in order that they may derive the greatest benefits from the scientific program.

The Scientific Program Committee is eager to receive suggestions as to how improvements can be made. Will you not send your comments and suggestions to the State Secretary?

* * *

HOTEL RESERVATIONS AT DEL MONTE

All hotel reservations on the Monterey peninsula for our 1937 annual session will be made through Mr. Carl Stanley, manager, Del Monte Hotel, Del Monte, California. Reservations will be confirmed in the order of receipt.

* * *

The Tactics of Opposition

1. *Be Noisy*

If the majority favors a plan, support it, but rage vociferously at the methods of the administration. Covertly obstruct. (This is called "deep stuff.")

2. *Make Lots of Noise*

Propose other plans. The more plans the greater confusion. (This is called "smoke screen.") If possible gather support for a plan that will defeat the whole movement. (This is called "counter-movement.")

3. *Be Loud*

Try to divide the supporters of the movement that you wish to obstruct or destroy. (This is called "the split.")

4. *Yell and Rage*

Challenge the sincerity of any or all leaders of the other side. (This is called "vilification.")

5. *Bewail*

Place yourself in a position where you may get bumped. Scream and cry at the terrible injury. This will excite some sympathetic support. (This is called "the squawk.")

6. *Roar*

Keep everybody as mad as possible. (This is called "inciting unrest.") Be quite careless with the truth, if necessary. Few take the trouble to investigate inflammatory allegations. (This is called "stretching it.")

7. *Rave*

Threaten and bull-doze. (This is called "throwing a scare" or "putting on the heat.") Occasionally let loose a dire prediction. The latter goes well. (This is called "auguring ill.")

8. *Moan and Groan*

Wear an air of deep suffering. (This is called "martyrdom.")

9. *Yawp*

When you see that the fight is hopeless, that the others are surely going to win out and that your cause is lost, claim all the credit. (This is called "getting on the bandwagon.")

10. *Side-Step*

Start something else. (This is called "staging a comeback.")—*Oregon Medical Reporter.*

Basic Science.—The importance of physiology and biochemistry in the mental equipment of the internist has been long conceded. Dr. Roscoe R. Graham, writes: "While skill must be an asset to the surgeon, yet if not accompanied by the knowledge and appreciation of the biochemical, physiologic, and psychologic disturbances inseparable from all disease processes, the results of such surgical procedures will leave much to be desired. Such an individual is merely an operator, a technician, carrying out stereotyped procedures—not a surgeon. The training of a surgeon has now become so complicated that the former presumably adequate knowledge of anatomy and surgical pathology must be supplemented by a training in biochemistry and physiology. To these sciences we are deeply indebted.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS[†]

County Hospitals

The following letter indicates what a member may accomplish by way of causing laymen to perceive facts bearing upon county hospitals:

May 20, 1936.

Dear Doctor Warnshuis:

After my conversation with you, I spoke before the Alhambra Farm Bureau last night on the doctors' side of the County Hospital Initiative. Mr. Anthony Crafton explained and advocated the initiative before I spoke. I had an audience of sixty very intelligent farmers and they were well impressed when I said the only objection the doctors had was that it would get in the hands of politicians and that we were absolutely opposed to the way it has been handled in Kern County. What the Farm Bureau advocates and thinks the act amounts to is quite a harmless affair that will allow the very poor, who cannot be classed as indigents, to get county hospital service for a small fee and that this would only be done through the social service investigators. All agreed with me that the act should be defeated if it would ruin the doctors or be made a political football. I told them that our experience has shown that the supervisors have taken advantage of it for politics and have erected extravagant county hospitals and the tax rate has been increased in those counties. I asked that they consult and work in coöperation with the Public Relations Committee of our County Medical Society and they said they would.

Many of the members of the Farm Bureau have bought stock in our local hospital and they insist that its future is more important than the initiative. They also want to have the local doctors secure and not under the mercy of the politicians. All were in favor of the act and most signed the petitions, but I think it will be easy to switch them over by November. I did not take a hostile attitude, and I think I made a good impression. They promised that they would see to it that it would be no political football and that the doctors would be safeguarded. I think that if we had reliable statistics we could easily convert them.

Sincerely,

(Signed) John L. Beard, M. D.

713 Main Street, Martinez.

County societies, through officers and committees, are requested to contact supervisors, granges, and farm bureaus and impart to their members actual facts. County hospitals management and administration must be removed from politics and taken out of the hands of politicians. Success in accomplishing this lies in the hands of all of our members. Every member must bend to the task and educate his patients and friends to oppose this political control of county hospitals.

* * *

Hospital Insurance

The House of Delegates of the American Medical Association at its Kansas City meeting went on record in endorsing the policies and principles adopted by the Department of Public Relations and the Council of the California Medical Association. The American Medical Association declared laboratory and x-ray services to be medical services and as such should be under the control of the medical profession. The American Medical Association also went on record in disapproving the invasion of medical practice by hospitals.

At the Coronado meeting our House of Delegates established a like policy, as will be seen by the report of the Reference Committee. There can now be no question as to Medicine's position in regard to this question as it relates to hospital insurance and the practice of medicine by hospitals.

[†] The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

COMPONENT COUNTY MEDICAL SOCIETIES

HUMBOLDT COUNTY

The Humboldt County Medical Society held their regular monthly meeting on the evening of June 3 at Saint Joseph's Hospital, President Woolford presiding. Twelve members were present.

We had as our guest, Dr. Joseph McCool of San Francisco, who spoke to us on *Strabismus as to Etiology and Treatment*. Doctors Holm, Gross and Charles Falk, Jr., discussed the paper.

Lawrence A. Wing, *Secretary*.

⁂

SAN JOAQUIN COUNTY

The regular monthly meeting of the San Joaquin County Medical Society was held in the Medico-Dental clubroom, Stockton, at 8:15 p. m., June 4. The meeting was called to order by President T. C. O'Connor.

The regular meeting was preceded by the customary supper meeting at the Hotel Wolf, at which twenty-seven guests and members were present. The paper at the supper meeting was given by Dr. C. A. Broaddus, who talked on *Balance of Eye Muscles*.

The minutes of the preceding meeting were read and accepted. The petition of Dr. Leo D. Smith for membership in the San Joaquin County Medical Society was passed on favorably by the Admissions Committee, and there being no objections from the floor, he was declared a member as of July 1, 1936. The petition of Dr. Henry C. Rixford for membership to the San Joaquin County Medical Society was presented and referred to the Admissions Committee.

Doctor Doughty spoke on the response obtained from the members for speakers for the Speakers' Bureau, and stated he would have speakers available for use any place in San Joaquin County.

Doctor Gallagos submitted a report for Doctor Kyddson, chairman of the Immunization Committee, who was not present. He stated that the Health Department would coöperate with the doctors by furnishing vaccines, but would not be able to allow any fees for those who could not pay physicians' fees. The nurse would contact the homes as usual and refer the parents to the family physician. He also stated that the monthly *Health Review* would have a slip attached, which Doctor Sippy requested the physicians to fill out if they had immunized any children, so the records of the Health Bureau might be complete.

Doctor Gallegos then reported on the formation of a mothers' clinic or birth control clinic started at the San Joaquin County General Hospital, Monday, June 8.

Delegates Broaddus and Powell reported on the recent convention at Coronado, and were of the opinion that the more populous counties had failed to give the less populous counties due consideration in their fight against the encroachments of the county hospitals on private practice of medicine.

The paper of the evening was presented by Ben Read, secretary of the Public Health League, who commented very forcibly on legislation impending and past. He told of the work of the League and stated they were organizing for the coming fights at the November election. Dr. Junius Harris, councilor of the California Medical Association, spoke on the problems confronting medicine in the State of California. Both of these papers and the reports of the delegates caused much lively discussion from the floor, many of the members entering into the comments.

After the discussion was closed, Dr. Dewey Powell moved that the activity of the San Joaquin County Medical Society on the impending fight against the County Hospital Bill be referred to the Board of Directors for formulation of plans and that the Society abide by these plans. This was seconded from the floor and the motion carried.

G. H. Rohrbacher, *Secretary*.

✠

Miner, Lucien Luttrell. Died at Los Angeles, June 5, 1936, age 58. Graduate of Columbia University College of Physicians and Surgeons, New York, 1904. Licensed in California in 1926. Doctor Miner was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

✠

Moore, Thomas Verner. Died at San Jose, June 6, 1936, age 53. Graduate of Creighton University School of Medicine, Omaha, 1911. Licensed in California in 1913. Doctor Moore was a member of the Santa Clara County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

OBITUARIES

Campbell Palmer Howard

1877-1936

Our members in attendance at the Coronado session gained and retained a most impressive opinion of one of the guest speakers, Dr. Campbell P. Howard, who conducted the Clinico-Pathological Conference at the second general meeting.

After the meeting Doctor Howard went to Los Angeles for a short visit with friends in Santa Monica. On June 3, near the approaching evening, he was seized with a sudden cardiac pain and expired in five minutes. His body was returned to Montreal.

Doctor Howard was born April 2, 1877. He obtained his B. A. in 1897 in McGill, and his M. D., C. M., in 1901 from the same university. He served his internship in Johns Hopkins, under Dr. William Osler. The years of 1902 to 1906 were spent in Europe in study. From 1910 to 1924 he was professor of medicine in the University of Iowa. Since then he has held the chair of clinical medicine in McGill University.

Doctor Howard was a frequent contributor to medical publications and collaborator in Osler's practice, Nelson's and Forscheimer's systems.

Upon his death the Association's condolences were wired to his family. The members of the California Medical Association regret the departure of this medical scientist and leader. Our regret is keener by reason of the fact that his end came shortly after his enjoyable and stimulating hours with us at Coronado as the guest speaker and leader in the Clinico-Pathological Conference at the Coronado annual session of the California Medical Association.

Wesley Wilbur Beckett

1857-1936

In the death of Dr. Wesley Wilbur Beckett, which occurred on June 3, 1936, the California Medical Association lost its president of 1909.

Born in Oregon seventy-nine years ago, of pioneer stock who crossed the plains, Doctor Beckett came to California at an early age, finally settling in San Luis Obispo County, teaching school there and afterward filling the position of assistant superintendent of schools.

In 1885 he entered Cooper Medical College, taking his first year there, but going to the University of Southern California for his last two years, graduating from that school in 1888, a member of its first class and becoming one of its most distinguished alumni.

Doctor Beckett built up a large practice in Los Angeles, and was recognized as one of its ablest surgeons. He filled many positions of honor and trust. He was president of the Southern California Medical Association in 1901, Los Angeles County Medical Association in 1904, Clinical and Pathological Society of Los Angeles in 1906, California Medical Association in 1909, and of the Association of Life Insurance Medical Directors in 1926. He retired from practice many years ago to give his entire attention to his position as medical director of the Pacific Mutual Life Insurance Company, an office which he had already occupied for some years previously. He was a vice-president of the company.

Doctor Beckett was always keenly interested in medical education. He became a trustee of the University of Southern California in 1895, a position which he held until his death. He occupied the chairs of obstetrics and gynecologic surgery at one time or another in the early school, but his greatest work in this connection, and what is probably his greatest monument, is the reorganization and reopening of the medical department of the University of Southern California in 1928. The University had conferred upon him the degree of LL. D. in 1927, "in recognition of his service in medical education."

In the passing of Doctor Beckett the city of Los Angeles has lost a distinguished citizen, the Los Angeles County Medical Association one of its oldest and one of its most valued members, the University of Southern California one of its ablest officers and most distinguished graduates, and the State Medical Association a valued and respected colleague.

Doctor Beckett was a man of warm personality, a sincere friend, a wise counselor, and a man of many benefactions.*

If you would live well in this world, strive to gain wisdom and to perfect your relations with your fellow men.—Leon J. Richardson.

THE WOMEN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

MRS. ANDREW J. THORNTON..............................President
MRS. ROBERT M. FURLONG..
....Editor and Chairman of Publicity

Report of the President

Dear Fellow Members:

A year ago I stood before the group of Auxiliary members who had assembled in session in Yosemite Valley and promised to fulfill the duties allotted to this office to the best of my ability. I have made every effort possible to do this.

In thinking over the situation on the start, I wondered, considering the very capable women who had preceded me, if there was anything left for me to do but to just oil the machinery. I was also reminded of an article that I had once read, entitled "These I Will Keep." The woman who had written it, instead of making New Year's resolutions at the beginning of the year, was taking stock of what was worth while in her life and deciding what she would keep.

We have been organized seven years. Each year has brought in its quota of progress, and as the years go on this should be the case. Each president finds some piece of work that especially appeals to her and that she considers important. As she approaches her year's work she needs to consider the outlook as a whole, selecting the most important activities and to herself say, "These I will keep."

I have not called my part in this program a report. I am leaving reports of the year's work to the chairmen and county presidents, believing that they should enjoy to the utmost the recountal of their own accomplishments. I can say that the work done by them has been of splendid value and that we may all be rightfully proud of their achievements.

Two weeks after our Yosemite convention last year, I left for our National convention at Atlantic City. That sounds like ancient history now and I shall not give you any details of that trip. Many of you have read my report of the activities of that convention. I want to say if any of you have just a lukewarm interest in our organization, I urge you to attend a National convention and become an enthusiast. It is stimulating to meet those interested women, hear reports from all over the United States and to mingle with that large Auxiliary group, remembering that we are all united for one purpose—the promotion of scientific medicine. I am so happy that Mrs. Thornton could enjoy the National convention just before taking up her duties as state president.

Believing that personal contact is a strong factor in helping the counties to realize that they are an important link in a larger organization, I made an effort to visit all the counties. California now has a total of seventeen organized counties. I visited and addressed fifteen of these counties. This meant miles of travel. Our counties are scattered all along the line from Siskiyou near the northern state boundary line to San Diego, a distance of seven hundred miles. Orange and Riverside, the two counties that I did not reach, were dated for an early visit in February, when I was to go south for a Board meeting. A telegram from our National president, Mrs. Herbert, saying that she would be in Oakland on these dates and in Los Angeles a little later in the month, caused us to change the date of our Board meeting, so I missed their meeting days. I was sorry indeed, but the nice president of Orange County, Mrs. Green, said that I would be just as welcome as a "past." So that is a leftover to which I shall look forward.

---

* See also item in June CALIFORNIA AND WESTERN MEDICINE, page 536.

† As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committtee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

It has been thrilling to have five new counties join us this year. On each occasion Mrs. Sargent has done the organizing. It gave me a feeling of satisfaction to visit these groups. Two of these counties are small and isolated: one is Lassen-Plumas, up in the high Sierra; the other, Siskiyou County. Both have fine, interested members. Marin is rather small in numbers, but I consider them just about ideal in the way they carry on their work. Fresno is another fine group. I did enjoy my trip to Fresno. The doctors' wives are the leaders in all civic affairs—fine public relations work, I would say. San Francisco has joined us, with a membership of two hundred. They are making splendid progress and, with all the opportunities that San Francisco has to offer, they will soon be making great strides.

By these contacts I have made rare friendships, and I hope that I may have been the medium through which the friendship of the state at large was brought home to them.

It was an enjoyable event this year to have our National president, Mrs. Rogers N. Herbert, visit our state. It is the first time that a National president has come to the West for a visit. Her first stop was in Oakland, where a luncheon was given in her honor, which the other northern counties were invited to attend. Representatives from six counties were present. Mrs. Herbert has a most pleasing personality, and her thrilling address was much appreciated by all present. She was also entertained in San Francisco, the guest of Mrs. Geiger. Later on in the week we had the pleasure of having Mrs. Herbert attend our State Board meeting in Los Angeles. That afternoon we all attended a very delightful tea arranged by Mrs. Barrow and sponsored by the Los Angeles group. Mrs. Herbert addressed this group also.

San Francisco and Alameda County women played an important part in the entertainment of the wives of the surgeons who convened in San Francisco in November. The Auxiliary members in Sacramento entertained the visiting physicians' wives at the annual meeting of the California Tuberculosis Association held in Sacramento in April.

During the year we have held our two Board meetings. The September meeting was held in Oakland, and the February meeting in Los Angeles. Fourteen members attended each meeting. Considering the long distance that some women had to go to attend the meetings, I was certainly pleased to have that number. We all enjoyed having Doctors Pallette and Barrow as guest speakers at the Los Angeles meeting.

It has been a great joy to work with the women who constitute my board. I am not trying to flatter when I say that it would be hard to find a group of women who would be so considerate and kind, coöperating in every way possible and doing, each one, her special line of work to the best of her ability. I treasure the friendships made among my board members.

In the reports you will hear in detail about our first Public Health Institute. The fact that it was given by my own county and in my own city was very gratifying to me. Also that it was such a successful venture .

I believe that Los Angeles County, under the leadership of Mrs. Barrow, has accomplished a most constructive piece of work—that of forming the assembly districts. This is of such importance that it cannot be ignored by the other counties. Fresno and Orange have followed the good examples of Los Angeles, and I hope by this time next year most of the other counties will do the same.

In talking with the members throughout the state, I was surprised to find that so many were a little vague as to what our *Courier* really is. In case there are some here today who do not know, let me say that it is the news sheet for the State Auxiliary, edited by our publicity chairman and published twice a year. An effort is made to have it reach every Auxiliary member. The cost is taken care of by the State. Last year it made its appearance for the first time, and as a single sheet. This year it has doubled its size. We have been commended very highly for this venture by National, who has suggested that more states follow our example.

I just cannot help but put in my little word about *Hygeia*. Such a wonderful magazine to put before the public to help strengthen our purpose! I wish to congratulate the smaller auxiliaries on their successful work with *Hygeia*. It is a noticeable fact that the smaller counties have made a much better showing than the larger counties in their promotion of *Hygeia*. I wish every one of you would go home from this convention with the determination to do your part to see that it has a larger circulation in your county.

We are closing our year on a good financial basis. We have not exceeded our budget. We have enjoyed the coöperation and support of the State Medical Advisory Committee at all times.

One of my ambitions this year has been to stress coöperation and friendship, without which no organization can reach its goal. My personal visits and the many letters written to officers and county presidents have helped to keep us in friendly accord.

It is my earnest wish that the members throughout the state will extend to Mrs. Thornton the same friendly gestures and coöperation that I have enjoyed. Let me say, in closing, that all through the year I never once forgot to oil the machinery. It has been a pleasure to serve my State. I thank you.

Mrs. Thomas J. Clark.

* * *

In Memoriam*

As we are enjoying this seventh annual convention, meeting old friends and renewing acquaintanceships made at previous ones, we are missing certain members who will never meet with us again nor with their own county societies, for during the past year they have been called "home," and we pause in our busy program to hold them in loving remembrance.

As fellow members they graciously made their contributions in many different ways. We are indebted to them and we miss them.

Let us turn, though, from the sadness of broken friendships to the consolation of happy memories and to the inspiration of their loyalty to and interest in our Auxiliary work.

There is much ahead of us now to be done—many lines of activity in this our work as doctors' wives, which challenge the best we have to give.

With the thought of these faithful ones in mind, and with the knowledge that time is fleeting, can we not best honor their memory by striving with enthusiasm toward those ideals which they held in common with us, and help advance the true light of scientific medicine in our spheres of activity?

Deceased Members—1935-1936

Alameda County—Mrs. C. G. Browne and Mrs. Daniel Crosby, both of Oakland.

Contra Costa County—Mrs. J. N. Bumgarner of Richmond.

Los Angeles County—Mrs. George K. Dasey of Santa Monica, Mrs. Franklin M. Dryden of Pasadena, Mrs. Vernon O. Heddens of Pasadena, and Mrs. Mary A. Smith of Whittier.

Marin County—Mrs. Carl W. Clarke of Ross.

San Diego County—Mrs. C. S. Marsden of San Diego.

If mankind were to make full use of its present knowledge of personal and public health, the expectancy of life could be increased from its present span of sixty years to seventy-five years, with a corresponding increase in personal happiness and efficiency, Dr. Dean Franklin Smiley, director of the Cornell University health service, told the Public Health Nursing Association of Rochester at a recent meeting.—*New York State Journal of Medicine*, February 15, 1936.

---

* Report made by Mrs. J. C. Condit.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column: California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

Pacific Northwest Medical Association, Portland, Oregon, July 8-11, 1936. C. W. Countryman, Medical and Dental Building, Spokane, secretary.

Pan-Pacific Surgical Congress. Honolulu, Hawaii, August 6-14, 1936. George W. Swift, M. D., 902 Boren Avenue, Seattle, Washington, president.

Medical Broadcasts*

The American Medical Association broadcasts have been discontinued for the summer months. A new series is under consideration for the autumn and winter of 1936-1937.

* * *

San Francisco County Medical Society.—The radio broadcast program for the San Francisco County Medical Society for the month of July is as follows:

Tuesday, July 7—KYA, 6 p. m.
Tuesday, July 14—KYA, 6 p. m.
Tuesday, July 21—KYA, 6 p. m.
Tuesday, July 28—KYA, 6 p. m.

* * *

Los Angeles County Medical Association.—The radio broadcast program for the Los Angeles County Medical Association for the month of July is as follows:

Saturday, July 4—KFI, 9 a. m. Subject: The Road of Health.
Saturday, July 4—KFAC, 10:15 a. m. Subject: Your Doctor and you.
Tuesday, July 7—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, July 11—KFI, 9 a. m. Subject: The Road of Health.
Saturday, July 11—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, July 14—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, July 18—KFI, 9 a. m. Subject: The Road of Health.
Saturday, July 18—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, July 21—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, July 25—KFI, 9 a. m. Subject: The Road of Health.
Saturday, July 25—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, July 28—KECA, 10:30 a. m. Subject: The Road of Health.

Alpha Gamma Mu Alpha.—A new society was born at Kansas City during the recent American Medical Association meeting—the A. G. M. A. (Alpha Gamma Mu Alpha), a postgraduate medical fraternity; secret, of course. Its object is to promote thought. It has no dues. Initiation fees are $1. Its members must belong to their County, State, and American Medical societies. Its meetings are held when and where the American Medical Association meets.

Its officers are: President, Arthur E. Guedel, 613 North Elm Drive, Beverly Hills, California; secretary-treasurer, LeRoy S. Peters, National Bank Building, Albuquerque, New Mexico; delegate, John W. Shuman, 3780 Wilshire Boulevard, Los Angeles, California.

Dean E. P. Lyon of the University of Minnesota Retires.—At the close of the present academic year, Dr. E. P. Lyon, Dean of the Medical School, retires from active service at the University of Minnesota. During his administration, covering a period of twenty-three years, the Medical School has exhibited steady and continued growth. As a fitting tribute to his stimulating leadership, the alumni and faculty of the Medical School propose to establish in his honor the Elias Potter Lyon Medical Lectureship at the University of Minnesota. The fund for this purpose is to be raised through subscriptions by alumni, faculty, students, and friends. Contributions to the Lyon Lectureship fund may be sent to Mr. William T. Middlebrook, Comptroller, University of Minnesota, Minneapolis.

Corrections in the U. S. P. XI.—Since the appearance of the new Pharmacopeia in December of 1935, the text has been subjected to intensive review and some corrections have been found necessary. In so far as these cover typographical errors or accidental inaccuracies, authority has been given to publish the list of corrections in pharmaceutical and medical journals.

Purchasers of the new Pharmacopeia may also obtain a printed list of these corrections for insertion in their copies of the United States Pharmacopeia. Send a three-cent stamp to cover postage to the publishers of the Pharmacopeia, the Mack Printing Company, Easton, Pennsylvania.

Questions have also arisen concerning certain pharmacopeial assays or tests, and these are under investigation. In those cases where it becomes desirable to revise any of the printed monographs such changes will be announced by "Interim Revision" procedure.

Industrial Accident Commission: Safety Department.—The committees that have been considering the Mine Safety Orders met in Los Angeles on May 25, 1936, and in San Francisco on June 4, 1936. The orders have been revised in accordance with the suggestions received at previous meetings of the committees and from other sources.

On May 27, 1936, the State Traffic Safety Advisory Committee met in the Biltmore Hotel, Los Angeles.

The second annual meeting of the Western Safety Conference will be held at Salt Lake City on September 21, 22, 23, and 24, 1936. The reports from B. D. Nebeker, Industrial Commissioner of Utah, are that twenty-two safety organizations have joined hands in making this an outstanding meeting.

In addition to the eleven western states (California, Oregon, Washington, Idaho, Montana, Nevada, Colorado, Arizona, New Mexico, Wyoming, and Utah) Baja California, British Columbia, and Hawaiian Territory have been invited to participate.

The Department of Public Health has released the figures for accidental deaths in California for 1935. Of the 477 occupational deaths listed, 142 were due to trade, 88 to agriculture, 67 to construction, and 60 to transportation and public utilities. Mining and quarrying were responsible for forty-eight deaths.

The necessity of each individual knowing how, when and where to swim is forcibly brought to light by the fact that 324 persons were drowned during the year. In the homes there were 251 deaths from conflagrations, burns and explosions, and falls killed 805; of the latter, 596 were to persons of sixty-five years or over.

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Fewer Homicides in California.—During 1935 there were forty fewer homicides than in 1934. There were registered with the California State Department of Public Health 435 homicides in 1934 as compared with 395 in 1935. Of the 395 such events that were recorded last year, 337 were murders and 49 were justifiable homicides, 30 by police officers and 19 by other individuals.

Most homicides are caused by firearms. Relatively few are caused by cutting and piercing instruments. The ready availability of firearms probably constitutes the most important factor in the production of homicides.

Out of 395 homicides reported last year 117 were in Los Angeles and 29 in San Francisco. There were 11 in Sacramento, 9 in San Diego, 7 in Stockton, and 7 in San Bernardino. The remainder were scattered throughout the state.

It will be noted that an average of more than one homicide occurs in California for every day in the year.

Federal Emergency Administration of Public Works in California.—The Public Works Administration program in California has reached a volume of 395 non-federal projects representing a total estimated cost of approximately $136,000,000, according to a special report made recently to A. D. Wilder, State Public Works Administration Director, 1210 Hewes Building, San Francisco.

That the Public Works Administration has spread a blanket of employment activity in the federal and non-federal divisions of its program over the entire fifty-eight counties of California, is the additional information contained in the report confirmed by the Public Works Administration's Division of Economics and Statistics in Washington.

Of the 395 non-federal projects widely distributed in California, 119 are entirely completed; 233 are in process of completion; and 43 are ready to start, excepting for a few details in the thorough preliminary preparations. A large proportion of the projects being built are nearly finished.

The number of projects and the amount of the total investment are about evenly divided between Northern California and Southern California. The bulk of the millions invested in the Public Works Administration permanent projects in California is in public school buildings, which comprise more than $58,000,000, or 43 per cent of the entire program.

The total number of projects is not regarded as truly representative of the magnitude of the work in California, in the opinion of the Public Works Administration officials. They state there are several multiple projects and cite as an illustration a single project in Los Angeles which includes four hundred school buildings.

A. D. Wilder, State Public Works Administration Director, emphasizes the fact that, of the estimated cost of $136,000,000 for the non-federal projects for California, the sum of $70,000,000 was put up by Uncle Sam's partners, in the shape of California's county and city governments, school or irrigation districts, or other similar bodies; and the balance of $66,000,000 by the Federal Government.

"The coöperation and teamwork between the Federal Government and the numerous local units of government in this Public Works Administration program in California has been most harmonious and effective," said Mr. Wilder. "In some instances, 70 per cent of the amount was provided locally; on other projects, 55 per cent of the estimated cost was borne by the authorized political or private unit.

"California Public Works Administration program has not only given employment to thousands of men and women on the sites of the projects, but the material orders have given employment to innumerable more thousands in the durable goods industries in this state and other states. California's part in the national program has been a mighty factor in stimulating additions to numerous payrolls in the heavy goods industries in the mid-West and East. Millions of California's and the Federal Government's dollars have bought materials to build enduring and beneficial public works in this state, as well as being the cause of hiring more employees on transportation systems and like auxiliary activities."

Julius Rosenwald Fund Report.—At the regular spring meetings of the Julius Rosenwald Fund concluded yesterday its trustees expressed gratification at the accomplishments of the Fund in coöperation with other agencies in making good medical care more available to people of small means. They expressed their continued interest in medical economics and their desire that programs in this field be carried forward effectively. During the past year plans for making medical care more available to people of small means have grown substantially. Voluntary insurance to lower the cost of hospital care—group hospitalization—has doubled now, covering some 350,000 persons, with plans being established monthly in new communities. . . . The Julius Rosenwald Fund, 4901 Ellis Avenue, Chicago, Illinois, will continue to assist in the extension of the insurance principle in relation to hospital service, in scientific studies concerning the cost and the organization of medical care and in the education of qualified personnel for studying and administering hospitals and clinics.

Federal Emergency Administration of Public Works. When one new employee is hired on a PWA project, four and a half new employees are added to the payrolls of industries supplying materials for that project, according to a survey received today by A. D. Wilder, State Public Works Administration Director, 1210 Hewes Building, San Francisco.

The special report was made to the California Public Works Administration state office by the United States Bureau of Labor Statistics in the Department of Labor, which had completed a study of a cross section of Public Works Administration operations in the form of six completed power projects which shows "that the indirect labor in relation to direct labor was four and one-half to one."

"We cannot place too much emphasis on the importance of the vast amount of indirect labor which is created by projects of the Public Works Administration in California," said State Public Works Administration Director, A. D. Wilder. "Our off-site employment is greatly in excess of our direct labor and equally, if not more, beneficial. Such facts are well shown by this special survey by the Department of Labor."

American College of Surgeons: Clinical Congress.—The twenty-sixth annual Clinical Congress of the American College of Surgeons will be held in Philadelphia, October 19-23, 1936, with headquarters at the Bellevue-Stratford Hotel. This will be the fifth congress in Philadelphia, and the American College of Surgeons is looking forward with great interest to viewing again the work of colleagues in that great medical center with its many fine hospitals, splendid schools, and large group of outstanding clinicians.

The Philadelphia Committee on Arrangements is planning a clinical program which will provide a complete showing of the surgical activities at the five medical schools and more than thirty hospitals that will participate. All branches of surgery will be represented therein. Among the special features of the clinical program are: (1) Cancer clinics, demonstrating treatment by surgery, radium and x-ray; (2) fracture clinics, presenting modern methods of treatment; and (3) clinics in traumatic surgery, demonstrating the newer methods of rehabilitation of the injured. A preliminary clinical program is presented in the current issue of *Surgery, Gynecology, and Obstetrics,* and in the June *Bulletin* of the College.

The Congress opens on Monday morning, October 19, with the annual hospital conference. On Monday evening, at the presidential meeting, the new officers will be inaugurated. The address of the retiring president, Dr. Donald C. Balfour, will be a feature of this meeting. On Friday evening, at the annual convocation of the College, Dr. Eugene H. Pool, president-elect, will deliver his inaugural address and the 1936 class of initiates will be received into fellowship.

At other evening scientific meetings and at various conferences during the week, eminent surgeons of the United States and Canada, with a number of distinguished visitors from foreign countries, will present and discuss papers on surgical subjects of timely importance.

Standards Set for Canned Dog Foods. — Effective June 3, 1936, all dog and cat foods packed in California must comply with state standards regarding quality of ingredients and labeling, according to an order issued by Dr. Walter M. Dickie, Director of the California State Department of Public Health. After this date, all such canned products that do not conform to the California Pure Foods Act will be seized wherever they may be found in the state.

It has been discovered that during the depression some underprivileged individuals began the practice of eating canned dog and cat foods because of the belief that their meat content was high. Recent investigations have revealed the fact that putrid inedible and diseased products are sometimes used in the manufacture of commercially packed dog and cat foods. In order to stop this practice, the state health authorities will hereafter regard as adulterated, within the meaning of the California Pure Foods Act, any canned dog and cat foods that consist in whole or in part of filthy, decomposed or putrid animal or vegetable substances, of any portion of an animal or vegetable unfit for food, whether manufactured or not, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter.

Such canned food must be packed in hermetically sealed containers and the contents must be wholesome and nutritious for dogs, cats or any domesticated animal. It may be composed of edible fresh, frozen or cured meat, meat by-products, or fish either wholly or in part. It may also contain cereals and other edible food products in permissible proportions provided that the presence of any or all of such are indicated on the label.

All such canned dog and cat foods that comply with the regulations must bear the following notations on the label: "Production Supervised by State of California Department of Public Health, Bureau of Cannery Inspection." Furthermore, the terms "fit for human food" or "fit for human consumption" are prohibited on the labels of canned dog or cat foods.

1936 Graduate Fortnight: New York Academy of Medicine.—For the annual graduate fortnight of the New York Academy of Medicine a subject of outstanding importance in the practice of medicine and surgery is selected and is presented from as many angles as possible. An attempt is made to offer to the profession a grasp of the advances in medicine so that the busy practitioner may be informed as to the last word on a given topic.

The ninth annual graduate fortnight will be held October 19 to 31, and will be devoted to a consideration of trauma; occupational diseases and hazards.

Twenty-three important hospitals of the city will present coördinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss various aspects of the general subject.

A comprehensive exhibit of books, pathologic and research material, apparatus for resuscitation and other first-aid appliances will be assembled. Demonstrations will be held at regular intervals.

Some of the features to be presented at the meetings, in the clinics, and in the exhibit, will be: First aid in industry, in the home, and on the highway; accidents and their management; resuscitation; shock and hemorrhage; hazards of athletics; general principles of fracture treatment; fractures of the extremities; injuries of the head, spine, abdomen, chest, and genito-urinary systems; hand injuries; burns—thermal, electrical, radiant, and chemical; medico-legal aspects of trauma and disability; war injuries and emergencies, including injuries caused by the high explosives, medical aspects of chemical warfare, gas attack, gas defense; carbon monoxid poisoning; fatigue and noise in industry; harmful conditions in industry; occupational diseases; occupational hazards; industrial poisonings; relation of trauma to disease.

The medical profession is invited to attend. A complete program and registration blank may be secured by addressing Dr. Frederick P. Reynolds, the New York Academy of Medicine, 2 East 103rd Street, New York City.

The Spirit of Science.—In 1870 Gaston Paris, eminent French philologist, wrote a letter to a German scholar from which the following quotation is taken. This letter was written during the Franco-Prussian War at a time when the city of Paris was under seige. Nevertheless, the Frenchman remained steadfast in his devotion to ideals as expressed in this communication to a citizen of an enemy nation. The late Dr. Herman M. Adler, at a conference of heads of state institutions in California, referred to the high ideals expressed in this communication.

"I profess absolutely and without reservation this doctrine: that science has no other object than the truth, and the truth for its own sake, without any care as to the consequences, good or bad, regrettable or fortunate, which that truth may have in practice. He who through a patriotic motive, religious, and even moral, allows himself, in the facts that he is studying, in the conclusions that he draws, the least concealment, the slightest alteration, is not worthy of holding his place in the great laboratory where probity is a claim for admission more indispensable than skill. Thus understood, the studies that we share, carried on with the same spirit in all civilized countries, form, above nationalities which are restricted, diverse, and too often hostile, a great fatherland which no war soils, which no conqueror threatens, and in which men's souls find the refuge and the unity that the City of God has given them in other times."

Tuberculosis Death Rate Lowered.—There were 4,516 deaths from tuberculosis registered in California last year as compared with 4,611 such deaths registered in 1934. The rate dropped from 74.9 per hundred thousand in 1934 to 72 per hundred thousand in 1935.

Of the 4,516 individuals who died of tuberculosis in California last year, 3,179 had lived within the state for ten years or more, 576 had lived in California from five to nine years, 357 had lived here from one to four years, and 186 tuberculosis decedents had lived in California for less than one year. By months the length of residence within the state of tuberculosis decedents last year was as follows: Under one month, 22; one to three months, 44; four to six months, 43; seven to twelve months, 77.

Of these deaths 4,105 were due to tuberculosis of the lungs, 131 to tuberculosis of the meninges, 103 disseminated tuberculosis, and the remainder were caused by tuberculosis of other organs of the body.

A true tuberculosis death rate for each community of the state is not available for the reason that many county institutions where tuberculosis deaths occur in great numbers may be located within cities, thus providing an abnormally high tuberculosis death rate for the city. If the county hospital is in the rural district an abnormally high tuberculosis death rate is provided for the county as a whole.

It is noticeable that tuberculosis death rates are higher in those counties where state hospitals and other hospitals are located. In those counties where there are many private institutions for the specific treatment of the tuberculous the death rates are inordinately high. In those cities that are known to be centers for casual laborers the death rate is exceptionally high. The same is true also of some of the southern counties where there are large numbers of Mexicans and other foreign-born who possess little or no immunity against the disease.

In consideration of the fact that untold numbers of tuberculous individuals migrate to California each year in the hope of finding benefits in a favorable climate, the low tuberculosis death rate for the state constitutes an enviable record. To be sure, it is much higher than that for most of the other states. That it should be maintained at so low a level in spite of the unprecedented migration to California is a matter of congratulation. Credit also should be given to those counties which maintain adequate machinery for the prevention of the disease and for the removal and isolation of active cases.

$5,358,760 in Social Security Checks Sent to Four States.—United States Treasury checks totaling $5,358,759.96 were issued to California, Wisconsin, Washington, and Iowa to cover the public-assistance grants to those states for the current quarter, April 1 to June 30, the Social Security Board announced recently.

California receives its first allotment of federal funds—$2,700,140.63—following approval of the state's old-age assistance plan by the Social Security Board on May 6.

Wisconsin receives a total of $1,272,790.83, which includes $945,000 for aid to the aged, $69,457.50 for aid to the blind, and $258,333.33 for aid to dependent children. Washington receives $700,703.50, consisting of $486,202.50 for aid to the aged, $39,501 for aid to the blind, and $175,000 for aid to dependent children. Iowa receives $685,125 for aid to the aged.

Thirty-four states and the District of Columbia have thus far taken advantage of the public-assistance provisions of the Social Security Act and are receiving federal aid in providing for their needy aged persons, blind persons, and dependent children. Federal contributions to these states for the three months ending June 30 are expected to total $18,500,000.

In order to qualify for federal funds, states must set up public-assistance plans which meet certain requirements specified in the Social Security Act and must submit their plans to the Social Security Board for approval. When a state plan for aid to the needy aged or the blind is approved, the Federal Government will pay half of any amount, up to a combined federal-state total of $30 a month to an individual, which the state grants to needy persons sixty-five years of age and over and to the needy blind, provided these aged or blind are not inmates of public institutions. The Federal Government also adds five per cent to its half in making its contribution. The states may use this additional amount for administering their plans, for cash payments to needy individuals, or for both.

Under approved plans for aid to dependent children, the Federal Government will match $1 for every $2 disbursed by the state for this form of assistance, up to a combined federal-state total of $18 per month for the first dependent child in a family, and $12 per month for each additional dependent child in the same family. Federal grants also include one-third of the state's administrative costs for this form of assistance.

LETTERS

Concerning article in "Time" in which American Medical Association and California Medical Association activities were mentioned.*

The Journal of the
American Medical Association
535 North Dearborn Street
Chicago

June 8, 1936.

Dear Doctor Kress:

Rock Sleyster has written to me relative to certain doubts which seem to exist in your vicinity relative to my relationships to *Time* magazine.

Just as soon as I read your editorial on *Time* magazine in last month's issue, I wrote a letter to Henry Luce. He apparently turned the letter over to Myron Weiss, who is in charge of science editing. I enclose herewith copy of my letter to Mr. Luce. . . . This should let you know where I stand in relationship to *Time* magazine.

Sincerely yours,
Morris Fishbein.

The Journal of the
American Medical Association
535 North Dearborn Street
Chicago

Mr. Henry R. Luce, May 19, 1936.
New York City.

Dear Mr. Luce:

During the last two months physicians everywhere have begun to comment on innumerable inaccuracies in the section of *Time* devoted to medicine. Moreover, the point of view relative to the American Medical Association and relative to the attitude of the majority of physicians of this country toward socialization and regimentation of medicine has occasioned some doubt as to where *Time* stands on this matter.

I feel that the question is of sufficient importance to bring to your attention the enclosed statement from California and Western Medicine, which is the official publication of the California Medical Association. Incidentally, I can affirm everything that California and Western Medicine says relative to the inaccuracies of the item which was published in *Time*.

Sincerely yours,
(Signed) Morris Fishbein.

* * *

American Medical Association

Chicago, June 10, 1936.

Dear Doctor Kress:

I am greatly obliged to you for your letter of June 1, to which is attached a leaflet on Group Medical and Hospital Service, reprinted from the *Los Angeles County Farm Bureau Monthly*. I shall send this on to our Bureau of Medical Economics.

I have just been informed that at the recent meeting of the California Medical Association a statement was rather freely made to the effect that the American Medical Association had something to do in some mysterious way with the publication of certain items which recently appeared in the magazine *Time*. Any such rumor is, of course, without any basis in fact. Unfortunately, some of our friends seem to be so constituted that they do not require facts to serve as a basis for rumors which they help to circulate.

I shall be delighted to see the account of the Coronado meeting in California and Western Medicine. I hope you had a splendid session.

With my sincere good wishes, I am

Very truly yours,
Olin West.

Concerning dinitrophenol and its dangers.

To the Editor:—I am referring to you a letter from the Cutter Laboratories stating their position in discontinuing the sale of dinitrophenol. In a conversation with their representative at the Arizona State Medical Association meeting at Nogales in April, 1936, I suggested that such ethical commercial laboratories as their own should discontinue the sale of this drug, on account of the unprecedented occurrence of cataracts in patients using dinitrophenol as a reducing medicine.

I was, therefore, pleased to learn from Dr. R. K. Cutter at the California State Medical Association meeting at Coronado in May that they had discontinued the sale of the drug.

You may have this correspondence for whatever publication you may desire to give to it in the interest of informing physicians of the dangers of the use of dinitrophenol.

Very truly yours,
Harold F. Whalman, M.D.

* * *

Dear Doctor Whalman:

Answering your letter of the 1st requesting our position in discontinuing the sale of dinitrophenol, I believe that this can best be done by quoting the letter which we send out when we refuse to fill orders.

> We appreciate your recent order for dinitrophenol, but regret that we are unable to fill it, as we have discontinued the sale of this drug.
>
> It was with considerable hesitation that we announced through the profession the availability of Dinitrophenol (Cutter). We did not do so because we thought the product had been proven, but rather because we knew that

---

* Note: Editorial comment was made in the May issue of California and Western Medicine (page 355) concerning certain mistatements in the lay magazine, *Time*, in which the American and California Medical Associations were mentioned. The article in *Time* led to considerable conjecture as to the possible source of the statements made. Here and there names of different persons were mentioned in connection therewith. It is therefore of interest to note that officers of the American Medical Association had the same point of view as our own as expressed in the editorial criticisms written for the May California and Western Medicine. A letter from Dr. Morris Fishbein, editor of the *Journal of the American Medical Association* and one from Dr. Olin West, secretary of the American Medical Association. are here given.

untested and improperly standardized dinitrophenol was not only being offered to the profession but was being advertised over the radio to the laity. We felt that the marketing of a properly tested and standardized dinitrophenol along strictly ethical lines and with the proper warning was a needed service.

Time has shown, however, that there may be delayed toxic effects from dinitrophenol which are unpredictable, and which seem to have little or no bearing on the purity of the drug or the method of administration. For this reason we believe that at present it should have no place in the field of medicine, outside of pure research, and have in consequence withdrawn Dinitrophenol (Cutter) from the market.

Yours very truly,
CUTTER LABORATORIES.

I also include a carton, and you will note that on the face of it it says, "This is a dangerous drug and should be taken only under the direct supervision of a physician." I feel sure that this discouraged a great many patients from self-treatment.

Very truly yours,
Cutter Laboratories.
R. K. Cutter, M.D.

SPECIAL ARTICLES

A. B. 246—NONPROFIT HOSPITAL SERVICE BILL*

CHAPTER 386

An act for the regulation and control of corporations organized for the purpose of operating nonprofit hospital service plans.

[Approved by the Governor July 5, A. D. 1935.]

The people of the State of California do enact as follows:

Section 1. This act shall govern any nonprofit corporation heretofore or hereafter organized under the laws of the State of California which by its original or by any amended articles is authorized to establish, maintain and operate a nonprofit hospital service plan whereby hospital care may be provided by said corporation to such of the public who become subscribers to said plan under a contract which entitles each subscriber to certain hospital care as provided in said contract, or whereby said hospital care may be provided by any hospital or hospitals with which said nonprofit corporation has or shall have a contract to furnish such hospital care to said subscribers provided that no such corporation operating under the provision of this act shall enter into any such contract with any hospital wholly or partly supported by taxation, except where such a hospital is the only hospital in the county where it is located, or is a hospital maintained and operated by or in connection with a State college or university of the State of California in conjunction with and as a part of its educational and administrative program; and provided further that no corporation authorized by the provisions of this act to establish, maintain and operate a nonprofit hospital service plan may itself furnish hospital care to its subscribers or do any of the acts herein authorized, unless and until it shall have first procured a certificate from the State Department of Puhlic Health certifying that it is complying with the standards required by said State Department of Public Health, nor shall any such corporation enter into any contract with any hospital for the furnishing of hospital care to its subscribers unless the hospital with which it contracts has procured such a certificate from the State Department of Public Health.

Sec. 1a. "Hospital care" as used in this act may include any or all of the following services: maintenance and care in hospital, nursing care, drugs, medicines, physiotherapy, transportation, material appliances and their upkeep.

Sec. 2. This act shall not apply to nor govern any corporation operating a hospital service plan on a profit basis, or which, though operating such a plan on a nonprofit basis, shall be organized for or shall conduct any business whatsoever on a profit basis, nor shall it apply to or govern any corporation formed and existing under the Constitution of 1849 pursuant to the act entitled "An act concerning corporations," passed April 22, 1850.

Sec. 3. Any nonprofit corporation organized to operate a nonprofit hospital service plan in the manner and in accordance with the provisions of this act shall be exempt from all other provisions of the insurance laws of this State, unless otherwise specifically designated herein, not only in governmental relations with the State but for every other purpose, and no law hereafter enacted shall apply to such a corporation unless it be expressly designated therein.

Sec. 4. At least two-thirds of the directors of such a corporation which shall furnish hospital care through contracts with hospitals as provided in Section 1 hereof shall be composed equally of duly appointed representatives of such hospitals and duly qualified and licensed practicing physicians holding a valid and unrevoked certificate to practice medicine and surgery or a physician and surgeon certificate, issued under the provisions of the State Medical Practice Act in the State of California. Such a corporation which shall itself furnish such hospital care shall choose its board of directors from such persons as it shall see fit.

Sec. 5. No corporation shall establish, maintain or operate a nonprofit hospital service plan as authorized by the provisions of this act unless it shall have first procured the written consent of the Commissioner of Insurance of this State to such establishment, maintenance and operation.

Sec. 6. The rates charged by such corporation to the subscribers for hospital care shall at all times be subject to the approval of the Commissioner of Insurance of the State of California, and all rates of payments to hospitals made by such corporation pursuant to the contracts provided for in Section 1 of this act shall be approved prior to payment by said Commissioner of Insurance.

Sec. 7. Every such corporation shall annually on or before the first day of March file in the office of the Commissioner of Insurance of this State a statement verified by at least two of the principal officers of said corporation showing its condition on the thirty-first day of December then next preceding, which shall be in such form and shall contain such matters as the Commissioner of Insurance shall prescribe.

Sec. 8. The Commissioner of Insurance, or any deputy or examiner or any other person whom he shall appoint, shall have the power of visitation and examination into the affairs of any such corporation and free access to all the books, papers, and documents that relate to the business of the corporation, and may summon and qualify witnesses under oath and may examine the officers, agents or employees of such corporation or any other persons in relation to the affairs, transactions, and condition of said corporation.

Sec. 9. All acquisition costs in connection with the solicitation of subscribers to such hospital service plan shall at all times be subject to the approval of the Commissioner of Insurance.

Sec. 10. The funds of any corporation subject to the provisions of this act shall be invested only in securities permitted by the law of this State for the investment of assets of life insurance companies and such securities shall be valued according to the methods used in valuing similar securities held by life insurance companies.

Sec. 11. Any dissolution or liquidation of a corporation subject to the provisions of this act shall be conducted under the supervision of the Commissioner of Insurance, who shall have all powers with respect thereto granted to him under the provisions of law with respect to the dissolution and liquidation of insurance companies.

VETERANS' HOSPITALS: THEIR PROPER AND IMPROPER USE

Lines were drawn today between disabled and unwounded veterans when M. A. Harlan, national commander of the Disabled Veterans of the World War, issued a brisk reply to the published statement of James E. Van Zandt calling for a general pension system.

Harlan, on behalf of his organization, expressed "unqualified and unreserved opposition" to the proposed pension law.

"We will neither sponsor nor support it," he said.

Asked if his opposition was not only the obvious position of an organization whose members now are benefiting from government compensation, Harland declared there was a difference between a pension—which he described as a "gratuity from the Government without regard to disability received, if any"—and a disability compensation for actual physical injuries received in the line of duty.

"Our position is not a selfish one," he said. "We have the interest of the entire taxpaying element of the country at heart, as well as our own. We believe the first obligation of the Government is toward its wounded veterans, and that the forthcoming economy drives in Congress will deprive worthy disabled veterans of their just consideration if there is also a movement on to pay a pension to all veterans.

---

* The nonprofit hospital service law, passed by the California Legislature in 1935 and approved by Governor Frank Merriam on July 5 was printed on page 175 of the August, 1935, issue of California and Western Medicine. Owing to the present interest in hospitalization insurance plans by many members of the Association, A. B. 246 (Chapter 386) is here reprinted. See also editorial comments in this issue (page 2).

"There were about 500,000 men wounded or disabled during the war, and of these only about 345,000 now are receiving compensation. And the total score of war's ravages has not yet been told. Medical authorities estimate that the peak of mental disabilities directly traceable to the war will not be reached until 1948."

HOW VETERANS' HOSPITALS ARE MISUSED

Harlan said that many industrial concerns have for several years been evading the responsibility for occupational injuries to their workmen by hospitalizing them in government institutions, regardless of whether or not disabilities were due to World War service.

"We would like to make the public conscious of the difference between a man disabled in the course of a dangerous industrial occupation, and a man disabled in the service of his country," the veteran leader added.

Of the $800,000,000 a year that is spent for pensions and compensations, less than one-third goes to World War veterans, Harlan said, more than one-third to Spanish War veterans, and most of the rest to veterans of the Civil War.—*Los Angeles Herald Express,* June 18, 1936.

TWENTY-FIVE YEARS OF LIFE SAVING

A comparison of deaths in California in 1911 with deaths in 1935 reveals the tremendous savings that have been effected in human lives during the past twenty-five years.

INFANTS

In 1911, 10.4 per cent of all deaths in the state were those of infants, but in 1935 the percentage of infant deaths was 5.5.

CHILDREN

In 1911, 6.9 per cent of all deaths were in children between the ages of one and fourteen years, while in 1935 the percentage of deaths in this age group was 3.3.

YOUNG ADULTS

In 1911, among individuals from fifteen to forty-four years of age the percentage of deaths to the total was 28.2, while in 1935 the percentage of deaths in this age group was 16.9.

THE PRODUCTIVE AGE

In 1911 the percentage of deaths among those fifteen to thirty-four years of age was 16.6 per cent, while the percentage among individuals of this age group in 1935 was but 8.9 per cent. Since tuberculosis in 1911 exacted heavy tolls among individuals in this age group, the remarkable reduction in tuberculosis mortality is to a large extent responsible for the savings here recounted.

ADULTS

The percentage of deaths among those over forty-five years of age increased in 1935 as compared with 1911, the percentages being 13 and 11.9, respectively. Among those fifty-five to sixty-five years of age the percentage increased from 13.1 in 1911 to 17.3 in 1935, and among those over sixty-five the percentage increased from 29.5 in 1911 to 44 in 1935.

It will be noted that the greatest life saving has occurred in the younger age groups among those under forty-five years of age. The effect has been to postpone the age of death, resulting in higher percentages of deaths among older people. The application of the principles of preventive medicine is largely responsible for this remarkable record. It is estimated that the population of California in 1911 was almost two and one-half million, and in 1935 it is estimated that the population was six and one-quarter million. In 1911, fourteen out of every one thousand persons died. In 1935, 11.5 individuals out of every one thousand population died. Had the 1911 death rate prevailed last year, there would have been 15,686 more deaths than actually occurred.

In commenting on longer and safer lives in the United States the *Illinois Health Messenger* recently stated that life is safer and longer in America than in any except the Scandinavian countries of Europe. People live from one to two years longer on the average in the United States than in England, France, Germany, or Italy. This is not due alone to a favorable natural environment, but to no small degree from the cultivation and utilization of preventive medicine.

The following table gives the total numbers of deaths in California by age groups and percentages of the total for the years 1911 and 1935:

Total Deaths by Age Groups

	1911		*1935*	
	Number	*Per Cent*	*Number*	*Per Cent*
Under 1	3,528	10.4	3,973	5.5
1–4	1,405	4.1	1,132	1.6
5–14	942	2.8	1,253	1.7

MUSSEL QUARANTINE ORDER ISSUED

The following quarantine order has been issued by Dr. Walter M. Dickie, Director of the California State Department of Public Health:

"A quarantine of all mussels from the ocean shore of California from the southern boundary of Ventura County north to the California-Oregon boundary, with the exception of the bay of San Francisco, is hereby established. All health officers and food inspectors are hereby instructed to enforce the provisions of this quarantine and to prohibit the taking, sale, or offering for sale, of mussels gathered in the district specified. This quarantine order shall be effective for the period May 19, 1936, to September 30, 1936.

"Said action is taken for the preservation of the public health."

This quarantine has been established annually for a number of years. It was issued earlier than usual this year because of two fatal cases of mussel poisoning of residents of Los Angeles who gathered mussels and ate them in Ventura County. Never before have poisonous mussels been discovered so far south in California. Heretofore the quarantine area has extended from Monterey County to the Oregon state line. Since the above quarantine order was issued it has become necessary, however, to include the coastal area of Los Angeles County and investigations are being made as far south as the Mexican border in order to determine if poisonous shellfish may be recovered in southern waters of California.

It will be noted that this quarantine will be effective until the end of September. Ordinarily the peak of toxicity in these shellfish comes about the middle of July. Early in the season the toxicity is comparatively low and after July it diminishes gradually, until by the end of September little or none is discoverable. It is important, however, that the provisions of this quarantine order be observed most carefully during the entire period. Some individuals are more susceptible to this type of poisoning than others, and small quantities of shellfish might produce marked symptoms of severe illness.

MORTALITY FROM CERTAIN DISEASES AMONG CHILDREN UNDER FIFTEEN YEARS OF AGE IN CALIFORNIA

1906–1934

By Walter M. Dickie, M.D.
San Francisco

PART III*

Among children under one year there are 456 deaths during the four-year period 1906-1909, with a rate of 309.7 per 100,000 group population. There has been a steady decrease in rates throughout remaining periods until 1930-

---

* Part I of this article was printed in the May issue of California and Western Medicine, page 454; Part II, in the June issue, page 542.

1934, when there are 324 deaths with a corresponding rate of 81.0 per 100,000 group population. This is a reduction in the mortality rate of 73.8 per cent. In the ages between one and four there are 640 deaths, with a corresponding rate of 113.3 per 100,000 group population in 1906-1909. This rises to 1,001 deaths, rate 118.5 during the next five-year period and then drops gradually to a low point in the mortality rate, 52.5 per 100,000 group population with 906 deaths. This represents a decrease in the mortality rate of 55.7 per cent under the high point of 1910-1914.

Mortality from Tuberculosis, 1906-1934

Years	Under 1 yr.		1-4 years		5-15 years	
	Number	Rate	Number	Rate	Number	Rate
1906-1909	456	309.7	640	113.3	580	43.9
1910-1914	641	295.2	1,001	118.5	893	42.9
1915-1919	442	175.3	988	96.8	1,063	43.3
1920-1924	480	161.7	927	74.8	1,095	35.0
1925-1929	426	121.2	1,090	72.6	1,143	28.7
1930-1934	324	81.0	906	52.5	1,003	21.8

Among those in age groups 5 to 14 the rate in 1906-1909 is 43.9 per 100,000 group population, with 580 deaths. Although the number of deaths is doubled during some of the next periods the rate never rises so high as in 1906-1909, and falls to a low point of 21.8 in 1930-1934, with 1,003 deaths during that period. The decrease in rate from 43.9 in 1906-1909 to 21.8 in 1930-1934 is 50.3 per cent, the lowest of any of the three age periods studied.

VENEREAL DISEASES

In children under one year of age, the venereal diseases play quite a conspicuous part. During 1906-1909 there are 176 deaths attributable to these causes, with a corresponding rate of 119.5 per 100,000 estimated group population. During the next five-year period (1910-1914) the number of such deaths rises to 378, and the rate is 174.1. This rate drops considerably during the remaining periods until in 1930-1934 we find 265 deaths and a rate of 66.3 per 100,000 group population.

In the group of children one to four years of age, the number of deaths from venereal disease is diminished sharply and the rate is almost negligible. It begins at 3.7 per 100,000 population with 21 deaths, then rises to 6.2 per 100,000 population with 52 deaths and from there decreases to 1.7 per 100,000 group population with 29 deaths during 1930-1934.

In age group 5 to 14 years, the trend is similar to that in age group 1 to 4 years, although the rates are very small. It is probable that many of those with congenital infection have died during the earlier age groups, and only a few hold over and die during this period.

Mortality from Venereal DIseases

Years	Under 1 yr.		1-4 years		5-14 years	
	Number	Rate	Number	Rate	Number	Rate
1906-1909	176	119.5	21	3.7	3	0.2
1910-1914	378	174.1	52	6.2	17	0.9
1915-1919	323	128.1	55	5.4	19	0.8
1920-1924	405	136.4	46	3.9	29	0.9
1925-1929	331	94.2	51	3.4	31	0.8
1930-1934	265	66.3	29	1.7	25	0.5

OTHER EPIDEMIC DISEASES

This group consists of the residue not included in the main groups of deaths treated separately. The diseases under this heading which produce the greatest number of deaths are erysipelas, tetanus, purulent infection or septicemia and the mycoses, which account for nearly the total number of deaths.

By far the highest death rate in this group of diseases occurs among children under one year of age, although there is not such a great discrepancy in so far as the actual number of deaths is concerned. During the period 1906-1909 there are seventy-one deaths of children under one year, or 48.2 per 100,000 group population. This rises to 236 such deaths with a rate of 79.5 per 100,000 group population during 1920-1924, and then falls to 127 and a corresponding rate of 31.8 per 100,000 group population in 1930-1934.

In children one to four years of age, the trend is similar to that among infants less than one year old, but the rates are much lower. Beginning with a rate of 6.2 per 100,000 group population and 35 deaths, it rises to a high of 123 deaths and a rate of 9.9 per 100,000 group population during 1920-1924 and then falls to a low of 77 deaths, with a corresponding rate of 4.5 per 100,000 group population during 1930-1934.

Among children 5 to 14 years of age, the rates are somewhat lower than among the two lower age groups, but in general the trend is similar. We find that there are thirty deaths during 1906-1909, with a rate of 2.3 per 100,000 group population, which rises to 200 deaths and a mortality rate of 6.4 per 100,000 group population in 1920-1924, and then falls to 169 deaths and a corresponding rate of 3.7 per 100,000 group population.

Mortality from Other Epidemic Diseases, Chiefly Erysipelas, Tetanus, Purulent Infection (Septicemia and the Mycoses), 1906-1934

Years	Under 1 yr.		1-4 years		5-14 years	
	Number	Rate	Number	Rate	Number	Rate
1906-1909	71	48.2	35	6.2	30	2.3
1910-1914	126	58.0	69	8.2	25	1.3
1915-1919	131	52.0	67	6.6	60	2.4
1920-1924	236	79.5	123	9.9	200	6.4
1925-1929	201	57.2	124	8.3	186	4.7
1930-1934	127	31.8	77	4.5	169	3.7

EXTERNAL CAUSES

This group of deaths follows closely those of the communicable diseases, and for that reason the study includes them as well as the infectious disease group. In all three age groups studied, the numbers of deaths are lowest during 1906-1909, but increase each period up to 1925-1929, and then fall slightly during 1930-1934. Rates increase in the two older age periods studied up to 1920-1925, and then decrease for the next two periods, the rates being slightly lower than in 1906-1909 in all instances.

In the group of children who died uder one year of age from external causes, there are 178 or 120.9 per 100,000 group population during 1906-1909. Both the number and the rate from deaths in this cause group increase until 1925-1929, when a high point is reached with 490 deaths and a rate of 139.4 per 100,000 group population. During 1930-1934 both number and death rate recedes to 422 and 105.5 per 100,000 group population, respectively.

Mortality from External Causes, 1906-1934

Years	Under 1 yr.		1-4 years		5-14 years	
	Number	Rate	Number	Rate	Number	Rate
1906-1909	178	120.9	459	81.3	585	44.3
1910-1914	270	124.4	761	90.1	853	43.4
1915-1919	307	121.8	929	91.0	1,106	45.1
1920-1924	406	136.7	1,150	92.8	1,510	48.3
1925-1929	490	139.4	1,285	85.6	1,787	44.9
1930-1934	422	105.5	1,089	63.2	1,643	35.2

Age groups one to four years shows 459 deaths and a rate of 81.3 per 100,000 group population 1906-1909, and then rises to a high point in numbers during 1925-1929 with 1,285 external deaths, but the high point in the death rate from external causes is reached during 1920-1924 with the rate of 92.8 per 100,000 group population. The lowest rate comes during 1930-1934, when there are 1,089 deaths with a rate of 63.2.

Age group 5 to 14 shows the largest number of deaths of any of the three age groups under study, but the rates are lower than in the other two groups because of the greater number of children exposed to the risk. Beginning with 585 deaths and a rate of 44.3 per 100,000 group population, the greatest number of deaths is found during 1925-1929, when there are 1,787 such deaths. The high point in rate comes in 1920-1924 with 48.3, but drops to 35.2 per 100,000 group population with 1,643 deaths during 1930-1934.

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 7, July, 1911

From Some Editorial Notes:

The American Medical Association Meeting.—As the annual meeting of the American Medical Association convenes [in Los Angeles] the day this number of the *Journal* goes to press, it is not possible to publish any matter relative to the meeting in this issue. At the time of writing, however, there is every prospect that the meeting will be largely attended, and that the California members will be there in considerable numbers. . . .

* * *

Salvarsan: New Indications.—With the increasing use of salvarsan, we now find scattered through the literature many reports of cases where various sorts of disturbances and even deaths have followed its injection. These reports might lead to an exaggerated fear of this, our most effective antisyphilitic drug, were they not subjected to most careful analysis and study. . . .

* * *

The California Association of Medical Milk Commissions.—For two years there has been held in connection with the meeting of the State Society, and at the invitation and expense of the San Francisco commission, a meeting devoted to the consideration of a pure milk supply. . . . Accordingly, there was formed at Santa Barbara the California Association of Medical Milk Commissions. The association is composed of the milk commissions of the county medical societies, and its purpose is to promote the use of certified milk and to assist in raising the general milk supply to a higher standard by dispensing literature on this subject, by illustrated lectures, by public meetings, and by personal work among the profession, the laity, and the dairymen. . . .

From an article on "The Experimental Basis of Vaccine Therapy" by Frederick P. Gay, M. D., University of California, Berkeley.

It would be rash indeed to attempt to outline the potential value of vaccine therapy, but one may sketch very clearly the historical path that has led to our present method of treating bacterial infections by injecting killed cultures of bacteria. When we later come to consider the rationale of this latest aspect of immunization, that is immunization employed as a therapeutic measure, we shall find ourselves stopping short of ultimate explanation, embarrassed not at any failure of the laboratory worker to respond to clinical demand, but by the fact that practice has outstripped theory, and not, it is to be feared, to the ultimate benefit of practice itself. . . .

From an article on "The Indications, Technique, and Results in Decompressive Operations on the Brain," by Wallace I. Terry, M. D., San Francisco.

The idea of trephining the skull for the relief of increased intracranial pressure is an old one—indeed, it is possible that the crude openings in the skulls of some prehistoric individuals were made for the purpose of relieving persistent headache due to tumor. The credit of advocating decompressive trephining for tumors of the brain which were not removable or could not be located is due to Horsley, although others had previously reported cases where such operations had been done. It was not, however, until Harvey Cushing, basing his ideas largely upon his experimental work on cerebral compression, empha-

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By Charles B. Pinkham, M.D.
Secretary-Treasurer

News

"Three swift raids on suspected Los Angeles, Hollywood, and Long Beach headquarters of a coast-wide illegal operation ring, extending from Seattle to San Diego, form the latest developments today in local investigation of the Syndicate's activities. More than a truckload of instruments and equipment valued at $150,000 were confiscated at the apparently hurriedly vacated offices. . . . All offices were under the name of 'Dr. George E. Watts,' police declared. Rolls of currency were found in the Los Angeles office, indicating it had been hurriedly vacated. Evidence of the nature of the business was found in the presence of more than fifty pieces of jewelry, apparently paid by women patients in lieu of cash. . . ." (Los Angeles *Evening News*, June 6, 1936.)

"The Federal Government yesterday stepped into the investigation of the alleged state-wide criminal operation syndicate, uncovered here last week. A representative of the Intelligence Unit of the Bureau of Internal Revenue called on Captain of Inspectors Charles Dullea, seeking all information police have gathered on the ring. . . . Three persons have been arrested here already, with warrants out for two others. Those under arrest are R. L. Rankin, alleged 'brain' of the syndicate; Sarah Lee, secretary to Dr. J. C. Ross; and J. C. Perry, Rankin's brother-in-law and local manager. Warrants are out for Doctor Ross and Dr. James Beggs, alleged to have been the Oakland surgeon for the ring. . . ." (San Francisco *Examiner*, June 7, 1936.)

"Correspondence, surgical instruments, and papers of Dr. Lawrence J. Giubbini (licensed chiropractor) wanted in connection with an alleged illegal operation ring, were seized here today by San Francisco and local police. . . . An Internal Revenue agent went with the officers seeking information in connection with income tax reports of Doctor Giubbine and his partner. . . ." (Associated Press dispatch, dated San Jose, and printed in the San Francisco *Call-Bulletin*, June 18, 1936.)

"Blanket felony indictments of thirty-one men and women, said to be members of a coast-wide illegal operation ring, were returned yesterday by the grand jury in Superior Judge Elmer E. Robinson's court. . . . Bail for R. L. Rankin, asserted ringleader of the group, and three other alleged principals—G. E. Watts, J. A. Creeth, and J. O. Shinn—were set at $5,000. Bail of Marvin Raithel, under arrest, and a witness at the grand jury hearing on June 10, was fixed at $500. The women's bail was set at $500, and the other doctors involved had bail fixed at $2,500. Besides Raithel and the four alleged leaders, the following were indicted: Valentine St. John, M. D., W. Norman Powers, M. D., Harry L. Houston, M. D., E. T. Pattee, M. D., James Beggs, M. D., J. C. Ross, M. D., L. J. Giubbini, D. C., G. B. Smith, M. D., Paul Robert de Gaston, William Byrne, Violet I. Rankin, J. C. Perry, Violet Pellegrini, Leola Habel, Ruth Hanson, Viola Warner, Laura Miner, Nedra Arden, Josephine Follet, Grace Cole, Bessie McCarthy, Lillian Wilson, Zora McEwen, Beatrice Bole, Mary Wilson, and Gladys Korf. . . ." (San Francisco *Examiner*, June 19, 1936.)

"Police carted two truckloads of evidence, assertedly bearing on operations of a supposed state-wide physicians'

Limited Facilities for Part-Pay Treatment

Few Physicians in United States Congress.—The interest of the average physician in the conduct of the political situation of the country reminds one of Mark Twain's remark about the weather. He said, "Everyone is criticizing it, but no one does anything about it." Medical men criticize conduct of local, state or national affairs, but if the present medical representation in Congress can be used as a criterion, the profession has almost entirely lost interest in politics.

Time was when doctors of medicine were not uncommon in the Congress of the United States. One of the ablest men who ever sat in the Senate was Joseph H. Gallinger, M. D., who represented New Hampshire in the House for four years, and in the Senate for over thirty years. No other physician ever reached the pinnacle of fame which was attained by Doctor Gallinger. He was not only one of the oldest men in point of service, but he was easily one of the most influential.

Since his day, with the exception of the senior Senator from the State of New York, no physician has long graced the halls of Congress. Senator Royal S. Copeland is the only representative of his profession in the Senate today, and he has but four confrères in the House of Representatives.

Senator Copeland, formerly of the medical faculty of the University of Michigan, and mayor of Ann Arbor, and later dean of New York Homeopathic-Flower Hospital Medical College, came into the public eye as the commissioner of health in the city of New York, a position he filled with unusual credit for five years. Doctor Copeland was looked upon as one of the most outstanding public health authorities in the country during his term of office, and he was rewarded for his splendid work by election to the Senate in 1923. Senator Copeland was reëlected in 1929, and again in 1935, making him one of the "older brethren" of that august body.

He had as an associate from 1929 to 1935, former Governor Henry Drury Hatfield, M. D., of West Virginia, one of the most prominent surgeons in that State. Unfortunately, the Senator was not reëlected, leaving Senator Copeland to carry the torch alone.

In the House of Representatives are to be found four medical Congressmen, three from the East and one from the Middle West. Dr. William L. Higgins of South Coventry, Connecticut, and a graduate of the University of the City of New York, 1890, represents the Second Connecticut District. He is a former president of the Connecticut State Medical Society; he served sixteen years in the General Assembly of his state, was secretary of state for four years, and was also a county commissioner and a selectman of Coventry. He was first elected to Congress in 1932.

The sole medical representative from the Corn Belt is William H. Larrabee, M. D., of Indiana, a graduate of the Indiana University School of Medicine, and a practitioner in New Palestine for thirty-three years. He belongs to the national, state, and county medical societies, is prominent in fraternal circles, and was formerly a member of the City Council, secretary of the County Board of Health, and a representative in the Indiana General Assembly. He is now serving his sixth year in Congress.

The State of New York has two physician-congressmen in the persons of Joseph L. Pfeiffer, M.D., F.A.C.S., of Brooklyn, and William I. Sirovich, M. D., F. A. C. S., of New York City.

Doctor Pfeiffer is a 1914 graduate of the Long Island College of Medicine, and is assistant surgeon to the Kings County and St. Catherine's hospitals. He recently sent to the Scientific Medical Institutione of Emergency Attendance at Leningrad, Russia, at the request of the Soviet Government, his survey of appendicitis from the years 1920 to 1932, a total of 4,176 cases. Doctor Pfeiffer is prominently connected medically with various of the leading institutions in Brooklyn.

Doctor Sirovich, a graduate of the Columbia College of Physicians and Surgeons in 1906, has been superintendent of the People's Hospital since 1917. He was first elected

MAPHARSEN

IN THE TREATMENT OF SYPHILIS

The outstanding feature of Mapharsen is its rapidly beneficial effect upon early syphilis. Disappearance of spirochetes occurs promptly. Healing of lesions is rapid and complete. Symptomatic improvement is most satisfactory. Positive Wassermann reactions are reversed in a large percentage of cases.

Over half-a-million injections of Mapharsen have been administered without any serious accident—no death has occurred following its use; serious nitritoid crisis has not been reported. Although mild cases of dermatitis may occur, the incapacitating exfoliative type is very rarely encountered. Reactions observed are usually of a mild nature; a slight reduction in the dose will ordinarily prevent recurrence.

Mapharsen is an efficient antisyphilitic agent—a distinct refinement in arsenical therapy.

●

Mapharsen (meta-amino-para-hydroxy-phenylarsine oxide hydrochloride) has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

to the Seventieth Congress in 1927, and has been very active in the House since that time. The Doctor is not only a member of various medical organizations and civic groups, but has been an official arbitrator in labor disputes and is much interested in child welfare and copyright matters.

This list constitutes the medical representation in Congress, but dentistry and pharmacy also have exponents in the Capitol.

The senior Senator from Minnesota, Henrik Shipstead, D. D. S., of Minneapolis, was graduated from the Northwestern University Dental School in 1903, and practiced his profession in Glenwood, Minnesota, until 1920, when he removed to Minneapolis. He still maintains an office in that city. The Senator was mayor of Glenwood for two terms, and was in the House of Representatives of his own state. He was first elected to the Senate in 1922, was reëlected in 1928 and in 1934.

In the House of Representatives are two dentists, Frank Crowther, D. M. D., of Schenectady, New York, and John M. O'Connell, D. D. S., of Westerly, Rhode Island.

Doctor Crowther was graduated from Harvard Dental School in 1898, and practiced in Boston until 1901, when he removed to Perth Amboy, New Jersey. In 1912 he went to Schenectady. In New Jersey Doctor Crowther was a member of the House of Assembly, and of the Middlesex County tax board. He was at one time president of the Common Council of Schenectady, and was first elected to Congress in 1919. He has served continuously in the House since that time, now being a member of the Ways and Means Committee.

Doctor O'Connell was graduated from the Philadelphia Dental College (now Temple University Dental School) in 1905 as the valedictorian of his class. He has practiced in Westerly since his graduation, except for sixteen months when he was overseas with the Twelfth Division. The Doctor is prominent in the life of Westerly and in the

VACATION TIME

S.M.A. is obtainable wherever vacations take parents in the United States.*

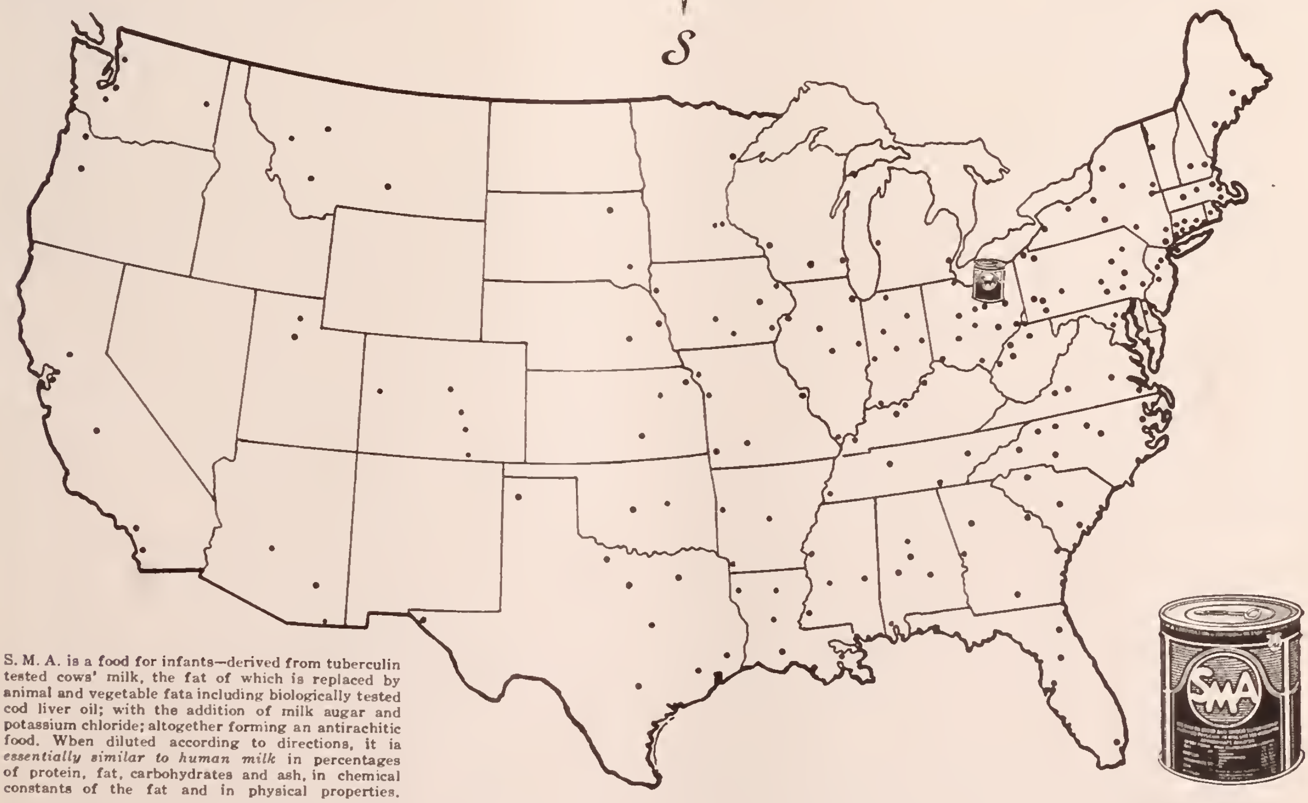
In addition to producing excellent nutritional results more simply and more quickly, S.M.A. has the advantage of availability in all parts of this country.

Parents need take only small quantities of S.M.A. with them when they travel, replenishing their supply as they go.

*S.M.A. is also available in Canada and many foreign countries. Details upon request.

From Maine to California, practically every wholesale drug house in the country carries stocks of S.M.A., and most of the 50,000 retail druggists stock it. In the cities, any retailer who runs out of S. M. A. can get it overnight, and druggists even in the remote rural districts can get S. M. A. quickly when their supply is exhausted. (The map shows locations of wholesale stocks. Retail outlets are too numerous to show here.)

S.M.A. babies are independent of local milk supplies. Wherever their parents may travel, they are assured of safe milk. S. M. A. and boiled water provide them a breast milk adaptation anywhere.



S. M. A. is a food for infants—derived from tuberculin tested cows' milk, the fat of which is replaced by animal and vegetable fats including biologically tested cod liver oil; with the addition of milk sugar and potassium chloride; altogether forming an antirachitic food. When diluted according to directions, it is *essentially similar to human milk* in percentages of protein, fat, carbohydrates and ash, in chemical constants of the fat and in physical properties.

(Continued from Page 36)

various fraternal groups. He is now serving his second term in Congress.

The sole representative of pharmacy is William D. Thomas, Ph. G., of Hoosick Falls, New York. He was graduated from Union College in 1904, went to the home town at once and continues to be the proprietor of the Thomas Pharmacy in Hoosick Falls. He was town clerk for eight years, a member of the legislature for two years, county treasurer for six years, and has twice been elected to Congress.

Our Canadian medical friends take their politics far more seriously. In the Canadian Senate today there are seven medical men; two each from Ontario and New Brunswick, and one each from Quebec, Manitoba, and British Columbia.

In the Federal House of Commons more than 10 per cent of the members who have been guiding the destinies of Canada during the past five years have been physicians. Twenty-nine out of the total membership of 245 were followers of Aesculapius. Ontario sent 14 physicians out of 82 Representatives to the Federal House; Quebec had 9 out of 65; Saskatchewan 2 out of 21; Alberta 2 out of 7; Manitoba 1 out of 17; and Nova Scotia 1 out of 12.

In addition to this, the provinces of Ontario and Saskatchewan each had a medical man as lieutenant-governor. Be it understood, the chief executive officer of all Canadian provinces is the lieutenant-governor.

Incidentally, the Canadian profession goes into politics in rather a big way. In the provincial legislature of Quebec out of ninety members eight are physicians; in Ontario there are six physicians among 112 members. In New Brunswick one-eighth of the legislature of forty-eight men are doctors. Nova Scotia has four medical members; Saskatchewan, four; British Columbia, three; Prince Edward Island, two; and Alberta, one.

Sixty-three physicians, representing various constituencies in the Dominion and serving at one time, indicate that the medical profession in Canada is determined that its representatives will be heard in the halls of legislation.

Toothaches of Primitive Man.*—That primitive peoples have perfect teeth and that civilized man has acquired his dental troubles because of eating refined foods are ideas which are frequently expounded by reputable scientists as well as by food faddists. There are two possible methods of testing the accuracy of such statements. One method is to study the skeletal remains of early man, and the other is to observe and record the dental condition of existing primitive peoples.

There are far too few specimens of the very early forms of man, such as the Java man, the Piltdown man, or the Peking man, available for the drawing of any conclusions concerning their freedom from dental disorders. It is known that the Neanderthal man, who lived in the last interglacial epoch, suffered from the ravages of pyorrhea. Relatively little weight could be placed upon any immunity to dental diseases in these early types of man since their tooth and jaw structure is quite different from that of the present species of man, homo sapiens.

It is probable that our present species of man, homo sapiens, has always been more or less subject to dental troubles. This may be correlated with the refinement of the bony and muscular structures of the face and jaw, which has allowed man to develop the extremely valuable accomplishment of articulate speech. The men who lived in France during the last glacial period were troubled with carious or decayed teeth. Many of the skeletons of men of this period show decayed teeth. More than 20,000 years ago, in North Africa there lived a white people of the Mediterranean subrace. The type skulls of this culture are in the collection of the University of Minnesota. One of these skulls has teeth in an advanced state of decay.

FREE PAMPHLET

Others show the teeth badly worn down by chewing coarse and gritty foods. Many teeth were lost during life and the jaw bones had been diseased.

In Germany caries were common during the Stone Age. One skull of a person living between the sixth and tenth centuries, B. C., exhibits the loss of all but five teeth during life. Of these five remaining teeth, four were carious. It has been estimated that in England, during both the Stone Age and the succeeding Bronze Age, from 10 to 20 per cent of the population suffered from caries. In predynastic Egypt, Ruffer found that 20 per cent of the population had caries, 60 per cent had chronic pyorrhea, and 30 per cent were tortured by abscesses about the roots of the teeth. About this same condition has prevailed throughout the historical period in Egypt.

Among primitive peoples of historic times the aboriginal Australians represent one of the most simple forms of culture. They had neither agriculture nor zoöculture. They ate such vegetable foods as they could find in natural gardens. Since they did not store food, their diet varied from season to season. The flesh of small animals, and even insects, supplemented the vegetable diet. Occasionally they had the flesh of the kangaroo. Krogman, in a study of a large number of pre-English invasion Australian skulls, found 8 per cent of the teeth to be carious, as contrasted with 27 per cent in a similar series of eighteenth century English skulls.

The Zuni Indians of Arizona have been an agricultural people for probably one thousand years. Their diet has been principally from their gardens, including corn, beans, and pumpkins, with the occasional addition of eggs or meat from the village turkey flock, or, even more rarely, the flesh of the rabbit or the deer. Leigh, in a study of Zuni skulls of about the time of the voyages of Columbus, found 75 per cent of the individuals to have had carious teeth, 52 per cent had abscesses around the roots of the teeth, and 56 per cent had suffered the ravages of pyorrhea.

The nomadic Sioux of the western plains lived upon meat, with the addition of wild fruits in season. They dried and stored some of the fruits for winter use. Leigh found the early Sioux to have the best teeth of any of the American Indians. Less than one-sixth of the population suffered from the various tooth disorders. In a study of an agricultural Algonquin tribe in Kentucky, he found another type of tooth trouble to be very prevalent. This was a widespread infection of the jaw bones, due to the exposure of the pulp of the teeth, which in turn was caused by the excessive attrition of gritty foods. These people lived largely upon corn, which was coarsely ground in stone mortars. He attributes the wearing away of the teeth to fragments of the stone mortars and to the large amount of silicious material in the hulls of the corn.

Stewart, after examining a large number of pre-Spanish Inca skulls from Peru, considered caries to be very prevalent. He found by count that, on an average, over 20 per cent of the molars were carious. This is in close agreement with the findings of Leigh for the Zuni tribe of Arizona, whose culture and food habits were similar.

The most perfect teeth among primitive peoples may well be those of the Bantu tribes of southern Africa. Shaw, in a study of a large number of Bantu skulls found only 4 per cent of the molars to be carious. This is in sharp contrast to the 20 per cent of carious molars in the Incas and the Zunis, and to the 40 per cent in present-day Americans and Europeans. The Bantus, in their undisturbed native culture, were largely a farming and cattle-raising people. Their diet included much milk, liberal amounts of meat, cereals, and vegetables as well as fruits in season.

The reasons for the greater incidence of tooth disorders in the civilized peoples of America and Europe than among primitive peoples are many and frequently obscure. The work of Hrdlicka and others with the Esquimos indicate that inherent racial differences in susceptibility to dental diseases may not be the answer. The effects of dental hygiene are difficult to demonstrate in the studies

Treatment of
Dermatitis Venenata
with Hollister-Stier
Poison Oak-Ivy Extract

Some of the outstanding advantages of Hollister-Stier Poison Oak-Ivy Treatments are:

1. They contain both the extracts of Poison Oak and Poison Ivy and are equally effective in immunizing against either one of these plants.

2. They are stable, therefore, the physician does not have to worry about using an impotent extract.

3. There is no pain or local reaction as a result of the administration of this extract.

of primitive peoples, but cannot be minimized. The effect of the clothing of civilized man in interfering with the absorption of the ultra-violet rays of the sun may be important in this respect. It is probable that there is an optimum amount of vitamin D required for the production of resistant dental enamel. From a study of primitive diets it appears that the total amount of minerals present in the food is not the important factor, but that the ability to utilize this mineral matter is the fundamental consideration. For example, the Sioux living on a low-mineral diet, but in a sunny climate, and wearing light clothing much of the time, had very good teeth. There is no evidence that a return to a diet heavy in coarsely ground and unbolted cereals would materially help the dental situation.

The lengthening of the average life with the advance of civilization must be considered when one compares the teeth of modern civilized man with those of primitive groups. Teeth which would be suitable for a life of thirty-five years may not be at all well adapted to a span of seventy years. The survival of weak individuals under the softer civilized conditions may also be a factor.

The following quotations from an article by Doctor Krogman in a recent issue of the *American Journal of Physical Anthropology* well sums up this subject. "When this correction (for carious missing teeth) has been made, and when age, sex, environmental and group homogeneity factors are considered, it willl be found that the difference in the frequency of dental caries is not so marked between early or primitive peoples and civilized peoples as is generally believed.

"Apparently, the so-called soft foods of the present age are not necessarily a contributing factor to dental caries, but, on the other hand, the coarse foods might cause serious tooth trouble."

THE POTTENGER SANATORIUM AND CLINIC

For Diseases of the Chest Monrovia, California

AN INSTITUTION FOR DIAGNOSIS AND THERAPY

CHOICE rooms and bungalows at rates ranging from $35 per week up, including medical service, general nursing, x-rays, routine laboratory examinations, ordinary medicines and therapeutic pneumothorax.

A few accommodations as low as $25 per week assigned on special application in selected cases.

In the foothills of the Sierra Madre Mountains, thirty-five miles from the ocean. Surrounded by beautiful gardens.

Close medical supervision. Aside from tuberculosis, special attention is given to asthma, bronchiectasis, lung abscess and kindred diseases.

Help for Hard-of-Hearing Children.—The Otologic Section of the California Medical Association has organized a committee of twenty members to study the problems of the hard-of-hearing in California, with particular reference to the early detection of impaired hearing among children. The outline suggested by the committee is as follows:

1. The development of a closer coöperation between the otologists and other agencies concerned with "Problems of the Hard-of-Hearing" (economic, social, educational).

2. The promotion of annual hearing tests by means of 4A audiometer for all pupils in public and private schools.

3. The establishment of classes for the teaching of lip-reading in all public and private schools in California; this to include classes for hard-of-hearing adults as well as children.

4. The scientific fitting and prescribing by qualified otologists of individual hearing aids for the hard-of-hearing.

5. The installing of group hearing aids in places of public assembly, *i. e.*, churches, theaters, public and school auditoriums, etc.

The chairman of the committee, Dr. Francis L. Rogers of Long Beach, states: "The otologists of California earnestly desire to coöperate in a 'work together' program for the prevention and cure of deafness. One in every ten persons in the United States is said to have impaired hearing. Most of this is preventable or curable. Every child who repeats his grade in school because of impaired hearing suffers a personal loss and the state suffers, in the aggregate, a huge economic loss. By united action California can and should lead the nation in a program which offers relief from much human suffering, a great social uplift and better opportunities for these handicapped citizens."

The members of the 1935-1936 committee are as follows: Doctors Harold A. Fletcher, section chairman (member ex officio), Medico-Dental Building, San Francisco; Dean E. Godwin, section secretary (member ex officio), 820 Professional Building, Long Beach; Isaac H. Jones, 1930 Wilshire Boulevard, Los Angeles; Frank A. Burton, Bank of America Building, San Diego; Frank S. Baxter, 1624 Franklin Street, Oakland; J. Roy Jones, California Western States Life Building, Sacramento; Peter A. Jordan, 241 West Santa Clara Street, San Jose; Dewey Powell, 242 North Sutter Street, Stockton; Joseph Chiapella, Chiapella Building, Chico; Harris D. Newkirk, Anaheim; B. F. Walker, Fresno; L. L. Henninger, Pasadena; Arthur W. Walker, Riverside; Ray M. Moose, San Bernardino; Harold L. Snow, San Pedro; William J. Mellinger, Santa Barbara; Fred E. Earel, Santa Ana; Robert C. Martin, Fitzhugh Building, San Francisco; Francis L. Rogers, chairman, 360 Junipero Avenue, Long Beach.

Cutting Their Fee.*—Doctors W. L. Crosthwait and W. L. Souther of Waco, Texas, literally "extracted" their fee from a wounded man whom they attended. In December, 1923, Jose Flores was riding a horse near Waco when a man with whom he had a quarrel rode up beside him, stuck a .45 revolver in his left side and fired. Due to the explosive effect of the bullet at close range the wound was very large, and in cleaning it out the doctors found pieces of clothing and a compact wad of foreign substance, which proved to be three $50 bills, folded tightly. The money, damaged, was turned over to a bank, sent to Washington for exchange, and the new money was tendered to the doctors as their fee. The patient, Flores, made a nice recovery and is still living.

United States Court Fines and Reprimands Manufacturer of Low-Strength Disinfectant for Hospital Use.—The Century Chemical Products Company, Detroit, Michigan, was fined $300 and rebuked by the court on May 15 in an action under the Federal Insecticide Act. The Food and Drug Administration, in comment on the action, says the company's product, known as "De-Germ," was offered as a disinfectant and germicide for use in theaters, hospitals, schools and other public places. It was tested by government bacteriologists and found to be ineffective against some of the commoner forms of bacteria, even when used full strength. Analysis showed it to be a weak solution of formaldehyd (1½ per cent), phenolic substances, soap and perfume materials in water (96 per cent).

Judge Lederle, in passing sentence, remarked that the penalties prescribed by the law are not adequate to punish the violation involved in this case. In his opinion, persons not trained in the testing and use of disinfectants should not be allowed to engage in their manufacture. None of the officers of the company, it developed, were so trained, and they employed no chemist or other experienced person who might make up for their deficiency.

Disinfectants, which are germicidal preparations, are subject to the Federal Insecticide Act, under a provision applying specifically to products claimed to be effective against "fungi that may infest vegetation or be present in any environment whatsoever." The law, of primary benefit to farmers and growers dependent upon agricultural insecticides and fungicides to guarantee a fair return on their investment, is thus shown to have a wide scope. It touches all classes of people. It is the view of the Food and Drug Administration that the seller of a so-called disinfectant for use in places where a weak or worthless preparation constitutes a major public health hazard, as in schools and hospitals, has not a proper regard for his responsibilities if he does not determine by thorough tests that his product is actually effective.

●

VITAMINS IN CANNED FOODS

I. VITAMIN C

● The history of scurvy is as old as the history of exploration and conquest. Its ravages among early explorers and invaders are recorded in the oldest pages of history, due principally to the fact that during extended sea voyages or treks by land, dependence had necessarily been placed almost entirely on foods preserved by the crude methods of the day.

Scurvy was the first vitamin deficiency disease to be controlled by dietary management. In 1757, Lind recognized the fact that some substance in foods exerted a specific protective action against scurvy (1). As early as 1804, the daily lime juice ration became compulsory in the British Navy (2).

However, it remained for modern biochemical science to establish the chemical identity of this antiscorbutic factor. Vitamin C is now known to be identical with cevitamic acid (levo-ascorbic acid) and is as yet the only vitamin to be synthesized in the laboratory (3).

There would appear to be no valid reason why scurvy should ever constitute a serious threat to the health of the average American infant or adult. Development of refrigerated transportation for raw foods and improvements in modern methods of food preservation, specifically canning methods, make available to the consumer during the entire year a large variety of foods possessed of valuable vitamin C contents. In addition, the modern trend towards education of the layman, in regard to the vitamin C requirements of both the infant and the adult, should also assist in complete eradication of infantile and adult scurvy from America.

Many canned foods are to be valued as contributors of vitamin C. Nutritional research has indicated that canned products such as the citrus fruits or citrus fruit juices (4), the more common fruits (5), and vegetables or vegetable juices, are important sources of the antiscorbutic factor (6). Modern canning procedures afford a good degree of protection to this labile vitamin, with the result that the canned food can be relied upon to supply amounts of vitamin C to the diet consistent with the amounts of the vitamin originally contained in the raw food from which it was prepared.

The Summer-Time Use of Mead's Oleum Percomorphum.—During the hot weather, when fat tolerance is lowest, many physicians have found it a successful practice to transfer cod-liver oil patients to Mead's Oleum Percomorphum.

Due to its negligible oil content and its small dosage, this product does not upset the digestion, so that even the most squeamish patient can "stomach" it without protest.

There are at least two facts that strongly indicate the reasonableness of the above suggestion: (1) In prematures, to whom cod-liver oil cannot be given in sufficient dosage without serious digestive upset, Mead's Oleum Percomorphum is the antiricketic agent of choice. (2) In Florida, Arizona, and New Mexico, where an unusually high percentage of sunshine prevails at all seasons, Mead's Oleum Percomorphum continues increasingly in demand, as physicians realize that sunshine alone does not always prevent or cure rickets.

Mead Johnson & Company, Evansville, Indiana, invite you to send for samples of Mead's Oleum Percomorphum for clinical use during the summer months to replace cod-liver oil.

Spray Residue Case Involves Important Test of Food Law.—Consumers of foods who look to the Federal Food and Drugs Act for protection have a stake in the outcome of litigation arising out of a seizure action under that act against a shipment of apple chops, an apple by-product, containing lead and arsenic spray residue. The United States District Court at St. Louis has just handed down a decision unfavorable to the Government. Consideration is being given at this time to the matter of seeking a review of the judgment of the trial court by way of appeal.

The Washington Dehydrated Food Company of Yakima, Washington, shipper of the consignment, contested the Government's allegations that the article contained added poisonous ingredients which might render it injurious to health. At the trial, testimony for the Government was presented by toxicologists and specialists who emphasized the potential danger to health involved in the continued consumption over a period of time of foods containing minute doses of lead and arsenic. One medical witness for the claimant admitted that, above a certain point of tolerance or quantity of lead which an individual can take up, he exhibits signs of intoxication from lead. Another medical witness for the claimant gave it as his opinion that the amount of arsenic and lead in these chops involved no public health danger. The president of the claimant firm testified that some susceptible individuals might, under certain conditions, be injured by the apple chops in question.

The Department of Agriculture has consistently maintained that foods containing added arsenic and lead in amounts held by qualified scientific opinion to be poisonous or deleterious constitute a definite menace to public health and, under the pure food law, are subject to action. As the result of intensive activities over a period of many years the Food and Drug Administration encounters today relatively few interstate consignments of fruits or fruit by-products containing dangerous quantities of lead and arsenic.

The Washington Dehydrated Food Company was found guilty in 1933 in the federal court in Yakima, Washington, of a violation of the Federal Food and Drugs Act in shipping in interstate commerce stocks of apple chops carrying residues of poisonous lead and arsenical sprays which might render them injurious to health. The firm later marketed apple chops containing lead and arsenic in amounts deemed by eminent toxicologists to be capable of injury to health. One of these shipments involved a consignment destined for export to France. The Government instituted seizure proceedings when lead and arsenic in such amounts were found, taking the position that the pure food law does not sanction the practice of making foreign countries a dumping ground for foods not measuring up to the criteria of fitness set for our own country. The lower federal court in that instance, however, ruled against the Government, holding that the shipment fell

within a proviso in the food law exempting, under certain conditions, violative shipments consigned to foreign shores. The court also expressed doubt as to the deleteriousness of the material.

An outgrowth of this adverse decision was the institution of a suit for damages by the president of the Washington Dehydrated Food Company against administrative officials of the Department of Agriculture who, in carrying out their duty, had reported the facts as to the arsenic and lead content of the export shipment. The civil suit for damages resulted in a hung jury and is of vital interest to every consumer, since in its larger aspects it involved the question as to whether a federal officer, in the discharge of his official duties under the Food and Drugs Act, can be held personally liable for damages for reporting facts to his superiors in the event of an adverse court decision under the Food and Drugs Act. The action in St. Louis is the most recent chapter in the various legal actions which have grown out of shipments by the Washington Dehydrated Food Company.

Illegal Drug Products.—The following prosecutions involving drug products in violation of the federal law also were terminated by the Federal Food and Drug Administration: Chicken Pharmacy, Petaluma, Calif., shippers of "C. P. Poultry Pox Remedy" and "Zink's White Diarrhoea Tablets," falsely and fraudulently represented as remedies for chicken-pox and intestinal troubles of poultry and chicks, fine $10; Dia-Bet Laboratories, Detroit, Mich., "Dia-Bet," a water solution of plant extracts including blueberry leaves, with sodium benzoate, offered as a treatment for diabetes, fine $400; Ehrhart & Karl, Inc., Chicago, Ill., "Sulfo-Kresol-Tabs," tablets containing oxyquinolin sulphate and lactose, but no cresol, represented as antiseptic and as a disinfectant, but found on test to be non-germicidal, for inflammatory conditions, septicemia and ulcerated throat, fine $50 and costs; Pearson Remedy Company, Burlington, N. C., "Old Indian

Herb Laxative," a water-and-alcohol solution of plant extractives including aloe (a laxative), for purifying the blood, for colic, acute indigestion, eczema, women's ailments, bad cough, sore chest, gall-stones, stomach trouble, pellagra, and boils, fine $100; Famous Mineral Water Company, Mineral Wells, Texas, "Dismuke's Famous Mineral Crystals," consisting entirely of Glauber's salt (a laxative salt) with certain accompanying impurities, for indigestion, auto-intoxication, stomach troubles, rheumatism, and excess weight, fine $100; Meyer Brothers Drug Company, St. Louis, Mo., two pharmaceutical preparations not meeting the standards of strength claimed for them on the labels, fine $400 and costs; Richard I. Morgan, Toppenish, Wash., "Zam-Ite," a product consisting entirely of powdered shale, for hardening of the arteries, heart disease, rheumatism, kidney diseases, stomach ulcers, worms, and children's diseases, fine $25; Price Drug Corporation, New York, N. Y., "Lassar's Zinc Paste," a product described in the United States Pharmacopeia and required by law to conform to that description, but in this case deficient in salicylic acid, fine $50; and Standard Pharmacal Company, Chicago, Ill., three substandard pharmaceuticals, fine $25 and costs. Terminations adverse to the Government included one case against the shipper of a so-called "rheumatic powder," twenty packages of which were seized in June, 1934, case *nolle prosequi* without comment by the court; and one against the shipper of dried apples alleged to bear spray residues in amounts dangerous to health, case tried before a jury, who returned a verdict for the defendant.

Psychiatrists tell us that there is a certain type of individual who overreacts to the stimulus of great danger. When confronted with the sudden danger of an automobile accident, for example, these persons instinctively throw out their arms and legs with such force that they step hard on the accelerator and sometimes cause a serious accident to happen.

The Mold Determines the Shape

—Molding Health Begins with the Diet Pattern

The iron caster is never surprised at the shape which the molten iron forms in his mold. He knows that it will follow the contour of the pattern he has impressed in the sand.

Molding health likewise follows a pattern—the diet pattern. Too often the formation of that pattern is a matter of chance. Merely to urge or recommend that the health pattern include a definite daily amount of milk is seldom enough to insure its use. There must be a more appealing element; and that element is **flavor.**

It is but natural for people, especially adults, to eat more willingly of those foods which "taste good." And, Golden State Milk does answer that taste-appeal.

No matter of chance, this fine flavor of Golden State Milk! It is the result of years of research and study in the feed and feeding procedure on California's finest dairy farms. That's why Golden State can likewise say with complete assurance that Golden State Milk is a "balanced" milk—rich in cream, of course, but rich below the cream line, too.

Perhaps, like those whom you advise, the idea of drinking milk does not appeal. Then, we urge you, try Golden State Milk. You'll be delighted and convinced.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

LIVERMORE SANITARIUM

The Hydropathic Department devoted to the treatment of general diseases excluding surgical and acute infectious cases. Special attention given functional and organic nervous diseases. A well equipped clinical laboratory and modern X-ray Department are in use for diagnosis.

The Cottage Department (for mental patients) has its own facilities for hydropathic and other treatments. It consists of small cottages with homelike surroundings, permitting the segregation of patients in accordance with the type of psychosis. Also bungalows for individual patients, offering the highest class of accommodation with privacy and comfort.

GENERAL FEATURES

1. Climatic advantages not excelled in United States. Beautiful grounds and attractive surrounding country.
2. Indoor and outdoor gymnastics under the charge of an athletic director. An excellent Occupational Department.
3. A resident medical staff. A large and well trained nursing staff so that each patient is given careful individual attention.

Has established and maintained a reputation, both among physicians and patients, for service and satisfaction.
Doctor: Send your next patient here, and you may feel assured not only that he will receive maximum benefit from his sojourn, but he will be grateful and will thank you for sending him to
SOUTHERN SIERRAS SANATORIUM

Many Deaths from Accidental Causes.—In 1935 there were 5,774 deaths in California due to external causes as compared with 5,567 such deaths in 1934 and 5,153 in 1933. This increase in 1935 occurred in spite of a reduction in the total number of motor-vehicle deaths and may be attributed largely to an increased number of falls in the home. Eight hundred five deaths last year were due to this cause as compared with 662 in 1934 and 660 in 1933. Almost half of all accidental deaths last year were due to motor-vehicle accidents and one-quarter of the total was due to accidents in the home.

Motor-Vehicle Deaths

Out of a total of 2,786 motor-vehicle deaths 1,043 were due to collisions with pedestrians, 854 to collisions with other motor vehicle, 200 to collisions with fixed objects, and 514 such deaths were in noncollision accidents. There were but eighty-seven deaths due to collisions with railroad trains, forty-eight with electric cars, thirty-seven with bicycles, and three with horse-drawn vehicles. Motor-vehicle deaths were quite evenly distributed among all age groups.

Deaths in Home Accidents

Out of a total of 1,398 deaths in this group, 805 were due to falls, 251 to conflagrations, burns and explosions, 93 to poisonings, 60 to absorption of poisonous gases, 43 to firearms, and 39 mechanical suffocations, 27 of which were in infants.

Considerably more than one-half of all deaths due to home accidents were in persons more than fifty-five years of age whose deaths were due to burns and falls.

Deaths in Public Accidents

In this group there were 1,045 deaths recorded last year, 324 of which were due to drowning, 211 due to falls, 118 railroad accidents, and 67 street-car accidents not involving motor vehicles. There were deaths in water transportation and forty-nine deaths in air transportation. The most important single cause of death in this group is drowning, almost one-third of the total being due to this cause.

Occupational Deaths

There were but 477 deaths in this group last year, 142 of which were due to accidents in general trades. Among other specific groups the following deaths were registered last year: agriculture, 88; construction, 67; transportation and public utilities, 60; mining and quarrying, 48.

AVAILABLE THROUGH ALL PHARMACIES
EMMENIN
The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)
IMPORTANT ANNOUNCEMENT . . .
By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.
DETAILS ON REQUEST
Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.
Manufactured by
Ayerst, McKenna & Harrison
(United States) Limited
Biological and Pharmaceutical Chemists
ROUSES POINT   NEW YORK
Available in liquid form in original 4-ounce bottles.
BROEMMEL LABORATORIES
SAN FRANCISCO

There were but thirteen accidental deaths in the manufacturing group and seven in clerical and professional service.

There are more than two hundred recognized means by which human life is terminated. Heart disease today leads all of them in the toll it takes.

President, Fred A. Shore, 704 E. Santa Clara Street, Ventura.

Secretary, A. A. Morrison, 625 Main Street, Santa Paula.

Yolo-Colusa-Glenn County Medical Society

President, T. E. Cooper, Davis.

Secretary, Ray E. Nichols, Woodland.

Yuba-Sutter County Medical Society

President, Francis P. Wisner, 715 Hart Building, Marysville.

Secretary, Fred W. Didier, Wheatland.

●

VITAMINS IN CANNED FOODS

II. VITAMIN D

• One of the most interesting chapters in the history of the science of nutrition is that relating to vitamin D. It is a record of steady advances in our knowledge concerning the vitamin. Starting with the work of Huldschinsky in 1919 on the ultraviolet irradiation of rachitic children; passing to the classical discovery in 1924 by Steenbock (1) and by Hess (2) that irradiated foods may acquire antirachitic potency; and extending through the profound studies of Windaus (3) and other investigators, on the constitution of the pure vitamin D obtained by ultraviolet irradiation of ergosterol, the story of vitamin D is a story of steady, scientific progress.

As a result of these basic contributions, there are available today a number of excellent standardized carriers of vitamin D. Viosterol, and the fish liver oils, and their concentrates, are readily available for use in the campaign against rickets whose prevalence, especially among infants in large urban centers, still remains high. In addition to these vitamin D carriers, the vitamin D fortified or irradiated foods have appeared within recent years.

It has become increasingly evident that there are a number of compounds which may promote calcification in the various animal species. It is further evident that these compounds vary in their physiologic efficiency with various animal species, or that they are "species specific". A number of forms of vitamin D have been postulated (4) and much research in the vitamin D field has been directed toward their isolation and identification.

In general, natural foods have never been regarded as important sources of vitamin D. The commonest food articles show extremely low antirachitic potencies when measured by conventional methods. However, recent evidence has been offered that the contribution of vitamin D made by a varied diet of canned foods may be more significant than has heretofore been supposed (5). While common foods admittedly cannot supply the high demands of infancy and childhood or other phases of the life cycle, for vitamin D, it would appear that they may supply significant amounts of the vitamin to the diet, especially in the case of the adult human, concerning whose quantitative vitamin D requirement comparatively little is known.

Biological research has shown that canned marine products such as salmon, shrimp, and oysters (6) make a small but definite contribution of the antirachitic factor to the diet. We desire to direct the attention of our readers to these interesting facts about canned foods in general, and these canned marine products in particular.

This is the fifteenth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Committee on Foods of the American Medical Association.

Woman's Auxiliary to the California Medical Association

State Auxiliary Officers

President, Mrs. A. J. Thornton, 2704 Twenty-ninth Street, San Diego.
President-Elect, Mrs. S. N. Weil, Rodeo.
First Vice-President, Mrs. Clifford A. Wright, 454 So. Irving Boulevard, Los Angeles.
Second Vice-President, Mrs. John V. Barrow, 142 South Windsor Boulevard, Los Angeles.
Recording Secretary, Mrs. Hobart Rogers, 1137 Mandara Boulevard, Oakland.

CO-OPERATE WITH YOUR ADVERTISERS

California and Western Medicine, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention California and Western Medicine.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this Journal to members and readers.

A SERVICE AGENCY—FOR READERS

The Journal of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in California and Western Medicine, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. California and Western Medicine and the A. M. A. Service Bureau desire to serve *you*.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE
(In affiliation with Cook County Hospital)
Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses; Intensive Two Weeks' Course starting October 5.

SURGERY—General Course, One, Two, Three and Six Months; Intensive Course, Surgical Technique every two weeks; Special Courses.

GYNECOLOGY—Three Months' Course, Intensive Two Weeks' Course starting September 21 and October 12.

FRACTURES AND TRAUMATIC SURGERY—Informal Practical Course; Intensive Ten Day Course starting October 12.

EAR, NOSE AND THROAT — Informal Course, Personal Courses; Intensive Two Weeks' Course starting October 5.

OPHTHALMOLOGY—Intensive Two Weeks' Course starting October 19.

UROLOGY—General Course Two Months; Intensive Course Two Weeks; Special Courses.

CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

General, Intensive and Special Courses in Obstetrics, Pediatrics, Tuberculosis, Roentgenology, Electrocardiography, Dermatology and Syphilology, Pathology, Neurology, Topographical and Surgical Anatomy, Physical Therapy, Gastro-Enterology, Allergy, Rectal Diseases, and Varicose Veins.

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL
Address: Registrar, 427 South Honore Street, Chicago, Ill.

Teeth and Health Are Closely Related.—It is now recognized that the health of the teeth and gums depends essentially upon nutrition, but their proper use and care cannot be overlooked. Carious or "rotten" teeth, and pyorrheas are the chief affliction.

Of the elements which go to make strong, healthy teeth, calcium and phosphorus stand foremost. It is also known that certain vitamins are necessary to steer the calcium and phosphorus into position in the teeth.

Calcium is found in largest amount and in most accessible form in milk. It is essential that all growing children should have one quart of milk a day in some form. Calcium is also found in green, leafy vegetables, but in a lesser amount. Phosphorus, however, is widely distributed. It is found in inexpensive foods such as whole grain cereals, beans and peas; also in lean beef, egg yolk, nuts and cheese.

Vitamin A is found principally in milk and butterfat, yellow root vegetables, egg yolk, and cod-liver oil. Vitamin C is found chiefly in oranges, lemons, grapefruit and tomatoes, fresh or canned. The teeth are the first part of the body to be affected by a shortage of vitamin C. A supply of vitamin D adequate for the growing child is probably not to be had during northern winters without the administration of fish liver oil (cod or halibut) or the equivalent.

The customary American diet of meat, potatoes without the peel, white bread, sugar and starches, and salt, lacks both sufficient vitamin and mineral elements. Milk, milk products and plenty of vegetables and fruit are essential to dental, as well as general bodily health. Finally, one should go to the family dentist twice a year for a check-up.

In sports and elsewhere you will do best by keeping body and mind relaxed. Go as fast as you like, but do not hurry.

CLASSIFIED ADVERTISEMENTS

Rates for these insertions are $4 for fifty words or less; additional words 5 cents each.

COACHING FOR STATE BOARDS—MEDICAL AND Dental. Arthur H. White, M. D., Suite 1005, Flood Building, San Francisco.

WANTED—MAN FOR LOCUM TENENS, OCTOBER 1 TO December 31. $250.00. General practice. Mid-Sacramento Valley. Address, Box 800, California and Western Medicine, 450 Sutter Street, San Francisco.

WELL EQUIPPED EYE, EAR, NOSE AND THROAT MAN, Age 43, at present practicing in large mid-western city, desires California location, associate or group. Excellent training here and abroad. Good health. PATHOLOGIST DESIRES APPOINTMENT ON PACIFIC Coast; four years' teaching experience (pathology); seven years director of laboratories, large hospital; is recognized surgical pathologist. 111, Medical Bureau (M. Burneice Larson, Director), Top Floor, Pittsfield Building, Chicago.

Santa Barbara County Wins Health Award.—In the new Rural Health Conservation Contest sponsored by the United States Chamber of Commerce and the American Public Health Association, Santa Barbara County won first prize in the western division of the United States and honorable mention was attained by Los Angeles County and Santa Clara County.

This contest is limited to counties in districts which have a full-time health service, and 160 such counties or districts were enrolled. The population included in the participating units is between eight and nine million.

For the purpose of the contest the United States is divided into six geographical divisions, three of which are east of the Mississippi River and three west of the Mississippi River.

The contest has as its purpose the elimination of premature deaths and prevention of resultant economic losses, together with those that may be due to unnecessary illness. It aims to accomplish this end by enlisting the active interest of business men in public health and by encouraging a more unified and coördinated program on the part of the several groups or organizations that may be engaged in the protection and promotion of the public health. The items on which participants are scored are similar to those selected for the scoring of cities except that problems peculiar to rural districts are particularly emphasized.

The joy of creation is so exalted that it has been called divine. Next to it is the joy of coming to know what has been wrought and thought by the most highly endowed members of the race. Through them and their achievements we discern powers and qualities latent within ourselves. The more we understand, the more we appreciate and the richer life becomes.

NUTRI-AD
ARTHROPHYLL
(6)
A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL (6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL (6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

New York: The Livingston Press, Livingston, Columbia County, 1936.

BOOK REVIEWS

Synopsis of Diseases of the Heart and Arteries. By George R. Herrmann, M. D., Ph. D., Professor Clinical Medicine, University of Texas. Pp. 344. Price, $4. C. V. Mosby Company, St. Louis.

On the title page the author lists his various special medical organization memberships but apparently thinks so little of his county, state and American Medical Association membership that he omits mentioning them.

The text is a good compendium of the subject for the medical student and general practitioner. It should serve only as a guide and reference to texts giving broader information on each subject.

Food, Fitness and Figure. By Jacob Buckstein, M. D. Pp. 252. Emerson Books, Inc., New York.

Essential, reliable information on the subject. Should be of interest to lay persons and will aid in refuting diet fads.

Eye, Ear, Nose and Throat Manual for Nurses. By Roy H. Parkinson, M. D., St. Joseph's Hospital, San Francisco. Third edition. Pp. 232. Price, $2.25. C. V. Mosby Company, St. Louis.

Just what its title declares. The nurse reflecting the information contained in this manual should become competent. Well arranged, good illustrations and well written.

Exophthalmic Goiter and Its Medical Treatment. By Israel Bram, M. D. Second edition. Pp. 456. Price, $6. C. V. Mosby Company, St. Louis.

The author's leaning is quite predominant throughout the text. No doubt intelligent study, supervision under medical treatment will arrest the symptoms and results of exophthalmic goitre. Persistence in medical treatment has brought irreparable damage. One must employ medical and surgical measures and this text will reveal what constitutes right medical care. However, one must not be misled by the author's success.

Medical Policies and Procedures for the Resident Staff of the Alameda County Hospitals and Clinics. Alameda County, California. By B. W. Black, M. D. Cloth. Pp. 236. Copyrighted.

Having been concerned with the composition and compilation of manuals for guidance of internes, residents and attending staff, this reviewer readily appreciates the value of this particular manual. It is indeed a very comprehensive and complete manual. All recommendations, regulations and procedures are concisely, yet clearly set forth. There is little to doubt or imagine. The entire scope of hospital medical care and treatment is well covered. Important factors are well stressed.

The manual reflects a well organized medical hospital service. It should be most valuable to other hospitals in preparing similar manuals for their institutions.

BOOK REVIEWS

(Continued from Preceding Page)

Essentials of Cosmetology. By H. O. Bames, M. D., Los Angeles. Pp. 98.

A handbook of concise and practical information for all who are interested in the maintenance or enhancement of the healthy appearance of the body.

The text consists of lectures given by the author to classes in public schools.

It should be a useful manual for cosmetologists and will go far in debunking certain claims and statements. Even physicians will do well to become informed upon these essentials and this guide will be found quite helpful.

Minor Surgery. By Frederick Christopher, S. B., M. D., F. A. C. S., Associate Professor of Surgery at the Northwestern University Medical School, Chicago; Chief Surgeon at the Evanston (Ill.) Hospital. With a foreword by Allen B. Kanavel, M. D., F. A. C. S., Professor of Surgery at the Northwestern University Medical School. Third edition, reset. Pp. 1,030, with 709 illustrations. Philadelphia and London: W. B. Saunders Company, 1936. Cloth, $10 net.

Surgery's tremendous and rapid strides deprives a teacher from imparting to medical students during their college and intern years the many practical procedures that experiences develop. The young doctor must acquire them but they must be possessed ere too many years of practice elapse.

This author has compiled these procedures in this text. He is sound and practical as well as thorough in his presentations.

Unreserved endorsement is made. This text should be on the desk of every physician and surgeon. It will be found to be a most dependable guide and consultant.

I shall try to correct errors when shown to be errors, and I shall adopt new views so fast as they shall appear to be true views.—Abraham Lincoln.

and before the appearance of albumin in the urine. Second, to show that by proper prophylactic treatment the toxemia may disappear in the large majority of cases, and that the true eclamptic seizure denoting a severe degree of toxemia may be prevented. . . .

From an article on "Arteriosclerosis: Review of Cases" by Donald J. Frick, M. D., Los Angeles.

The cases chosen for review were all private cases that have been watched for periods of from one to five years. The symptoms of each were due to the arteriosclerotic changes or accompanying hypertension; none were accepted that had prominent symptoms due to other conditions. . . .

From an article on "Urology—Past, Present, and Future" by M. Krotoszyner, M. D., San Francisco.

The first meeting of the recently formed Section on Urology of the San Francisco County Medical Society marks an epoch-making event in the history of urology on the Pacific Coast. This occasion—all-important and welcome to those of us whose interests and efforts are bent toward this hitherto neglected branch of scientific medicine—should not be permitted to pass without a few appropriate remarks upon the past, present, and future aspect of urology. . . .

Wisdom consists in knowing what to do. Skill consists in knowing how to do it. Virtue consists in doing.—David Starr Jordan.

When we find the thing for which we are best fitted, work is an unending joy.—Leon J. Richardson.

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 216)

"Dr. Edward H. Anthony today stood acquitted of a charge that he had issued prescriptions for narcotics illegally. The action was taken in Federal Judge Leon R. Yankwich's * court after a jury which had heard the case several months ago had failed to reach a verdict. Doctor Anthony declared he had issued drug prescriptions only to persons entitled to them under the law and in the course of his duties as a physician." (Los Angeles *Herald and Express*, June 24, 1936.)

"First steps for the return of L. J. Giubbini and Violette Pelegrini from Seattle, to face charges in connection with the state-wide illegal operation ring, were completed today in Sacramento. Governor Frank F. Merriam signed extradition papers for the return of the couple, also known as Mr. and Mrs. Victor Angelo, to San Francisco, according to the International News Service. Indicted by the grand jury along with more than a score of others, the couple are said by police to have fled north." (San Francisco *Call-Bulletin*, June 30, 1936.)

"Dr. S. B. Smith, one of thirty-one persons indicted here as members of a coastwise illegal operation ring, has been arrested in Albany, Oregon, police were notified. Assistant District Attorney John McMahon will go to Albany to arrange extradition, it was announced." (San Francisco *News*, June 24, 1936.)

"Dr. Paul Dorosh, Lindsay chiropractor, has been cited to appear before Judge E. B. Gould this morning at 10 o'clock to answer to a charge of violating Section 15 of

When Steers Had Long Horns

THE medicinal value of the glands of internal secretion was not recognized.

But times have changed, as well as cattle. Now, the therapeutic value of certain gland products is definitely established and each year adds to our knowledge in this important field of therapeutics.

To the physician prescribing gland products we urge specification of "Wilson," because it connotes a product made at the source of supply from fresh glands, processed promptly, with the aim of conserving maximum hormone activity, in a laboratory devoted exclusively to the endocrine field.

the State Chiropractors' Law, which requires the use of the initials 'D. C.' after the name when the title 'Dr.' is used. Doctor Dorosh was arrested yesterday morning on a complaint filed by George E. Swanson, the state inspector." (Lindsay *Gazette*, June 12, 1936.)

"Dr. Jesse C. Ross, 1080 Eddy Street, alleged principal in a coastwide illegal operation ring, surrendered at the city prison yesterday on an indictment charging conspiracy to perform illegal operations. He was released on $2,500 bail. . . . " (San Francisco *Examiner*, July 9, 1936.)

"East Bay police yesterday held Mrs. Amelia Mohr, 52-year-old Alameda widow, for investigation of charges that she performed an illegal operation. She was arrested on information given by Mrs. Clara Gottschalk, 35, of 1850 Eleventh Avenue, Oakland, who lay near death at Alameda County Emergency Hospital. . . . Mrs. Mohr was arrested at her home, 2244 Encinal Avenue, and taken to the office of Assistant District Attorney Charles Wehr." (San Francisco *Examiner*, July 3, 1936.)

"Police and Federal agents today joined in a search for members of a coastwide ring of fake eye doctors, reported to be operating on well-to-do elderly Los Angeles residents. Word that the ring had centered operations in Los Angeles after bilking victims in the State of Washington and other northern sections of thousands of dollars, followed on the heels of the report of a San Fernando couple that they had been defrauded recently." (Hollywood *Citizen-News*, July 7, 1936.)

A Modern Product

Of Proved Value in . . . the Endotoxic Infections

Edwenil, the polyvalent antibacterial agent, while comparatively new, has already been used so extensively that it has won the place of a leader in the treatment of the endotoxic infections such as the respiratory diseases, boils, measles, etc.

It is a stable, colloidal, protein-free (by the Biuret Test) solution for intramuscular injection.

Edwenil promptly raises resistance to the endotoxic infections but causes no detrimental reactions, either local or general. It can be used daily to advantage. Send for complete literature on

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

"Pleading guilty to violation of the medical practice act, Dr. Grover Talbott, San Jose chiropractor, today paid a $500 fine in Justice Grandin Miller's court. Talbott was accused by Mrs. Rose Toretta of 391 Empire Street, here, of performing an operation upon her last March, which nearly cost her life and left her a cripple. Doctor Talbott paid the fine in preference to a sentence of 100 days in jail." (Press dispatch dated San Jose, July 15, printed San Francisco *Examiner*, July 16, 1936.)

"Information received through a girl operative today resulted in two raids by police on establishments of an alleged abortion ring and the arrest of five women and three men. The places raided were 431 Ashbury Street, where Inspector George Engler said preparations were being made to perform an operation, and 1115 McAllister Street. Arrested and held on charges were Mrs. Minerva Geddes, Mrs. Frances Zoffell, William and Raymond Zoffell, her husband and son; Mrs. Raymond Brandt, Mrs. Gertrude Bergeron, Mr. and Mrs. Walter Swindell. Police said Mrs. Swindell was also known as Leila Geddes, sister of Minerva. The investigation grew out of the death of Mrs. Florence Alves, 38, Redwood City, mother of two children, in a San Francisco hospital, where she was taken for treatment following the illegal operation. . . . Mrs. Geddes, Mrs. Frances Zoffell, Raymond Zoffell and Mrs. Walter Swindell were charged with two felony conspiracies to commit abortion and attempt abortion. . . . " (San Francisco *Call-Bulletin*, July 16, 1936.)

"A jury in Department 40 of the Superior Court yesterday returned a verdict of 'guilty' against Dr. George H. Wymann, 44-year-old physician. The man, on trial for committing an abortive operation on comely Sylvia Carr that resulted in her death last May 11 in the General Hospital, was visibly affected by the jury verdict. Doctor Wymann, who was arrested by Detective Lieutenants Corsini and Clark shortly after the death of the woman, steadfastly denied having committed an illegal operation on the dead woman. Witnesses, however, came forth and told the court that the doctor had treated the woman while she was pregnant. The physician admitted to the arresting officers that he had treated the woman shortly after she was sent to the hospital. General Hospital attaches aided the police inquiry by pointing out that the dead woman had been subject to an abortion. . . . " (Los Angeles *Eagle*, June 26, 1936.) Doctor Wymann's medical license was remoked October 23, 1924, for narcotic dereliction, and restored October 17, 1927, when he was placed on five years' probation.

Pasteurization does not interfere with the food value of milk. It is true that overheating may throw out a small amount of casein and mineral salts, but this is negligible. The only important effect of pasteurization on the food value is the destruction of vitamin C, but since milk originally does not contain enough vitamin C for an adequate supply, tomato juice and orange juice must be given to babies.

for immunization

REFINED DIPHTHERIA TOXOID

[ALUM PRECIPITATED]

Lederle

This agent for active immunization against Diphtheria simplifies the immunization procedure in that only one injection is used.

Tissue absorption proceeds so slowly that the antigenic stimulus is maintained over a long period of time—simulating in effect the primary and secondary antigenic response obtained with two injections of plain Toxoid.

Refined Diphtheria Toxoid (Alum Precipitated) *Lederle* produces protective immunity in approximately 90% of children within 2 months.

It can be given to individuals under 8 years of age with confidence that only a very occasional child will suffer an objectional reaction. Children of more than 8 years, and adults should be tested with diluted Toxoid for sensitivity to this product (Moloney Test).

Supplied in two concentrations:

One Immunization—One 1 cc. Dose
One Immunization—One ½ cc. Dose

Packaged as follows (either concentration)

1 Immunization in 1 Vial
10 Immunizations in 10 Vials
10 Immunizations in 1 Vial

Sensitivity Test (Toxoid diluted 1:20)

10 Tests in 1 Vial
100 Tests in 1 Vial

A. Naso-lacrimal duct closed by congested mucosa.
B. Naso-lacrimal duct open and draining after application of vaso-constrictor.

THE first consideration in treatment—relief from the symptoms of nasal congestion, lacrimation, sneezing—may be secured promptly by the topical application of

NEO-SYNEPHRIN
HYDROCHLORIDE
(levo-meta-methylaminoethanolphenol hydrochloride)

Neo-Synephrin affords an effective vaso-constrictor which is of particular value in hay fever because it is always active, even when used repeatedly.

OTHER ADVANTAGES OF NEO-SYNEPHRIN INCLUDE:

1. Less toxic in therapeutic doses than epinephrine or ephedrine
2. Action more sustained than epinephrine
3. Free from sting

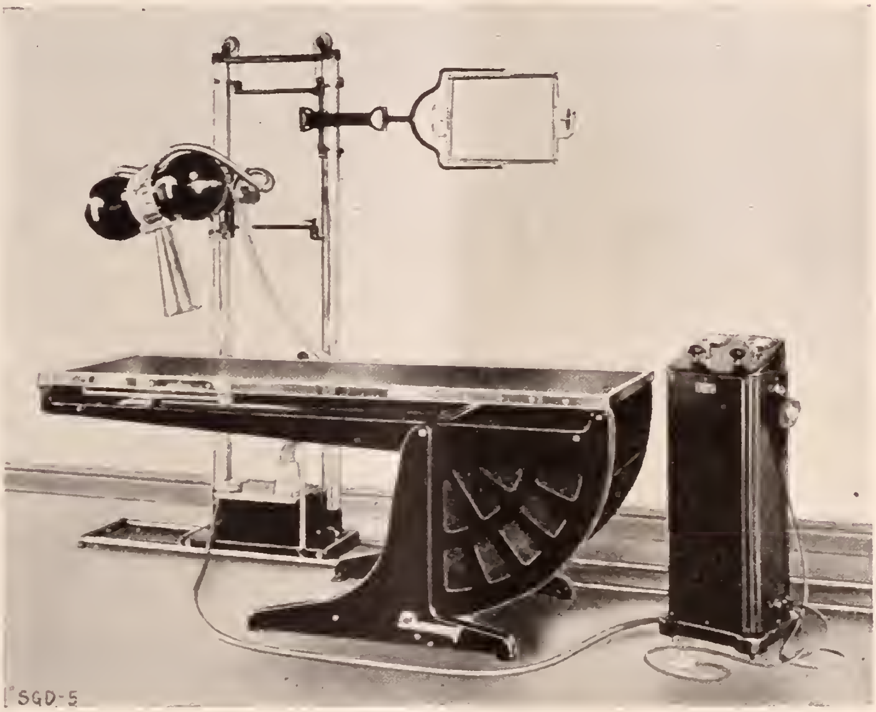
R. L. SCHERER COMPANY
X-Ray Sales and Service



The SGD-5 Power Plant

Shown above is the new Shock-Proof x-ray plant. Unquestionably the most flexible unit on the market. The counterbalanced tilt table, equipped with Potter Bucky diaphragm, is adjustable from Trendelenburg's position to vertical position.

SPECIAL FEATURES

Eighty-one point auto-transformer control, pre-reading milliamperemeter, four position stereoscopic shift, unobstructed fluoroscopic field from head to foot.

Visit our x-ray department and ask for demonstration of this marvelous unit. We carry a complete line of x-ray equipment and supplies. Our x-ray service department is at your command for repair work, for modernizing or shock-proofing your equipment.

Government Loses Diabetes Remedy Case.—In a trial at Denver, Colo., last week the Federal Government was defeated in its attempt to prove that Horace Wayne Pierce, manufacturer and shipper of a dried herb medicine called "Diaplex," was guilty of fraud under the criminal clause of the Food and Drugs Act. The herb used by Pierce is known in the semi-arid regions of the West as "salt bush," and to scientists as Atriplex canescens. It was packaged and labeled as a treatment for diabetes, a disease that physicians regard as amenable to control only by insulin and dieting. The acquittal of the defendant resulted, it is believed, because the jury was not convinced of the fraudulent intent, which, under the law, must be shown in all criminal cases involving curative claims for medicines.

Doctors experienced in the treatment of diabetes testified for the government that "Diaplex" could not affect the course of the disease. Their testimony is corroborated, officials state, by the unanimous opinion of medical men in the United States and elsewhere who have studied diabetes and its treatment. The breakdown in the government's testimony came when two of its witnesses—one a doctor—both of whom had used the preparation, admitted on cross-examination that shortly after starting the use of "Diaplex" they wrote to Pierce, the proprietor, in a complimentary and optimistic vein, stating they were pleased with results. At the trial Pierce claimed he depended on those letters as expressions of opinion from persons competent to judge the effects of his treatment. Since one came from a physician who had used the preparation in his hospital, and the other from a woman sufferer from diabetes who used it on herself, the jury concluded that Pierce was not guilty of fraud, despite the testimony of both witnesses that they eventually decided they had been misled, as the herb in fact turned out to be worthless in the treatment of their diabetes.

The Federal Food and Drugs Act prohibits the interstate shipment of a drug product bearing any medicinal claim that is false and fraudulent. The falsity of the claim for treating diabetes made for this medicine was fully proved, the government contends, but the charge of fraudulent intent was not sustained. Physicians appearing for the government said that diabetes varies in severity, some forms being capable of control by mere diet restriction, while others require both dieting and insulin. "The injection of insulin is an unpleasant task," said Dr. M. A. Hodgson, medical officer of the Food and Drug Administration, who attended the trial. "An herb tea is more agreeable and is taken up hopefully by patients who often mistakenly interpret its effects on certain symptoms."

The outcome of the prosecution, it was said at Administration headquarters, does not alter the official stand on such claims as were made for "Diaplex." Action will be brought against all interstate shipments of misbranded remedies, and against their shippers.

CONSTRUCTIVE TREATMENT FOR THE SPASTIC CHILD

The Tucker School has a seven-year record of marked improvement in even the most difficult cases of spastic children. Our method includes occupational therapy and applied psychology in a sympathetic, understanding, home-like atmosphere, under the personal supervision of Lillie Tucker, R. N., and Jeanne Cox, child psychologist. Prospectus sent on request.

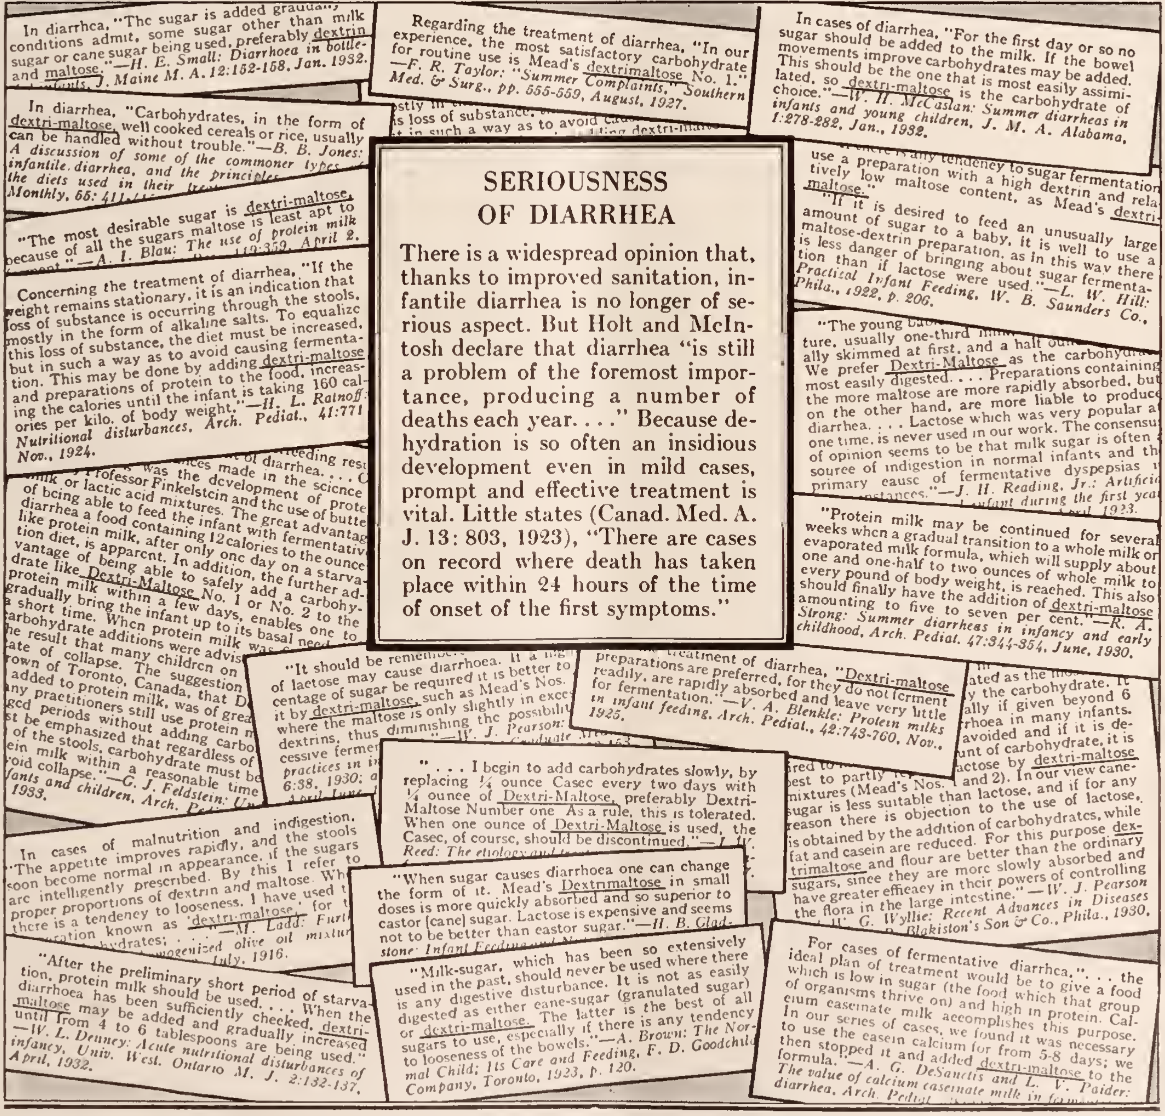
DIARRHEA

"the commonest ailment of infants in the summer months"

(HOLT AND McINTOSH: HOLT'S DISEASES OF INFANCY AND CHILDHOOD, 1933)

One of the outstanding features of DEXTRI-MALTOSE is that it is almost unanimously preferred as the carbohydrate in the management of infantile diarrhea.



In diarrhea, "The sugar is added gradually,
conditions admit, some sugar other than milk
sugar or cane sugar being used, preferably dextrin
and maltose."—*H. E. Small: Diarrhoea in bottle-*
J. Maine M. A. 12:152-158, Jan. 1932.

In diarrhea, "Carbohydrates, in the form of dextri-maltose, well cooked cereals or rice, usually can be handled without trouble."—*B. B. Jones: A discussion of some of the commoner types of infantile diarrhea, and the principles*
the diets used in their
Monthly, 55: 411

"The most desirable sugar is dextri-maltose,
because of all the sugars maltose is least apt to
—*A. I. Blau: The use of protein milk*
April 2.

Concerning the treatment of diarrhea, "If the weight remains stationary, it is an indication that loss of substance is occurring through the stools, mostly in the form of alkaline salts. To equalize this loss of substance, the diet must be increased, but in such a way as to avoid causing fermentation. This may be done by adding dextri-maltose and preparations of protein to the food, increasing the calories until the infant is taking 160 calories per kilo. of body weight."—*H. L. Ratnoff: Nutritional disturbances, Arch. Pediat., 41:771 Nov., 1924.*

of diarrhea. . . .
was the development in the science
Professor Finkelstein and the use of prote
milk or lactic acid mixtures. The great advantag
of being able to feed the infant with fermentativ
diarrhea a food containing 12 calories to the ounce
like protein milk, after only one day on a starva-
tion diet, is apparent. In addition, the further ad-
vantage of being able to safely add a carbohy-
drate like Dextri-Maltose No. 1 or No. 2 to the
protein milk within a few days, enables one to
gradually bring the infant up to its basal need
a short time. When protein milk was
carbohydrate additions were advis
the result that many children on
state of collapse. The suggestion
Brown of Toronto, Canada, that D

longed periods without adding carbo
must be emphasized that regardless of
of the stools, carbohydrate must be
protein milk within a reasonable time
avoid collapse."—*G. J. Feldstein:*
infants and children, Arch.
1933.

In cases of malnutrition and indigestion,
"The appetite improves rapidly, and the stools
soon become normal in appearance, if the sugars
are intelligently prescribed. By this I refer to
proper proportions of dextrin and maltose. Wh
there is a tendency to looseness. I have used t
preparation known as 'dextri-maltose,' for
hydrates; . . .—*M. Ladd: Furt*
homogenized olive oil mixtur
July, 1916.

"After the preliminary short period of starvation, protein milk should be used. . . . When the diarrhoea has been sufficiently checked, dextri-maltose may be added and gradually increased until from 4 to 6 tablespoons are being used."—*W. L. Denney: Acute nutritional disturbances of infancy, Univ. West. Ontario M. J. 2:132-137, April, 1932.*

Regarding the treatment of diarrhea, "In our experience, the most satisfactory carbohydrate for routine use is Mead's dextrimaltose No. 1."—*F. R. Taylor: "Summer Complaints," Southern Med. & Surg., pp. 555-559, August, 1927.*

SERIOUSNESS OF DIARRHEA

There is a widespread opinion that, thanks to improved sanitation, infantile diarrhea is no longer of serious aspect. But Holt and McIntosh declare that diarrhea "is still a problem of the foremost importance, producing a number of deaths each year. . . ." Because dehydration is so often an insidious development even in mild cases, prompt and effective treatment is vital. Little states (Canad. Med. A. J. 13: 803, 1923), "There are cases on record where death has taken place within 24 hours of the time of onset of the first symptoms."

"It should be remembered
of lactose may cause diarrhoea. It a
centage of sugar be required it is better to
it by dextri-maltose, such as Mead's Nos.
where the maltose is only slightly in exce
dextrins, thus diminishing the possibilit
cessive fermen
—*W. J. Pearson:*
practices in in
6:38, 1930;

treatment of diarrhea, "Dextri-maltose
preparations are preferred, for they do not ferment
readily, are rapidly absorbed and leave very little
for fermentation."—*V. A. Blenkle: Protein milks*
in infant feeding, Arch. Pediat., 42:743-760, Nov.,
1925.

". . . I begin to add carbohydrates slowly, by replacing ¼ ounce Casec every two days with ¼ ounce of Dextri-Maltose, preferably Dextri-Maltose Number one. As a rule, this is tolerated. When one ounce of Dextri-Maltose is used, the Casec, of course, should be discontinued."—*J. W. Reed: The etiology and*

"When sugar causes diarrhoea one can change the form of it. Mead's Dextrimaltose in small doses is more quickly absorbed and so superior to castor [cane] sugar. Lactose is expensive and seems not to be better than castor sugar."—*H. B. Gladstone: Infant Feeding and*

"Milk-sugar, which has been so extensively used in the past, should never be used where there is any digestive disturbance. It is not as easily digested as either cane-sugar (granulated sugar) or dextri-maltose. The latter is the best of all sugars to use, especially if there is any tendency to looseness of the bowels."—*A. Brown: The Normal Child; Its Care and Feeding, F. D. Goodchild Company, Toronto, 1923, p. 120.*

In cases of diarrhea, "For the first day or so no sugar should be added to the milk. If the bowel movements improve carbohydrates may be added. This should be the one that is most easily assimilated, so dextri-maltose is the carbohydrate of choice."—*W. H. McCaslan: Summer diarrheas in infants and young children, J. M. A. Alabama, 1:278-282, Jan., 1932.*

use a preparation with a high dextrin and rela
tively low maltose content, as Mead's dextri-
maltose."

"If it is desired to feed an unusually large amount of sugar to a baby, it is well to use a maltose-dextrin preparation, as in this way there is less danger of bringing about sugar fermentation than if lactose were used."—*L. W. Hill: Practical Infant Feeding, W. B. Saunders Co., Phila., 1922, p. 206.*

"The young
ture, usually one-third
ally skimmed at first, and a half
We prefer Dextri-Maltose as the carbohydr
most easily digested. . . . Preparations containing
the more maltose are more rapidly absorbed, but
on the other hand, are more liable to produce
diarrhea. . . . Lactose which was very popular a
one time, is never used in our work. The consensu
of opinion seems to be that milk sugar is often
source of indigestion in normal infants and th
primary cause of fermentative dyspepsias
—*J. H. Reading, Jr.: Artifici*
infant during the first yea
1933.

"Protein milk may be continued for several weeks when a gradual transition to a whole milk or evaporated milk formula, which will supply about one and one-half to two ounces of whole milk to every pound of body weight, is reached. This also should finally have the addition of dextri-maltose amounting to five to seven per cent."—*R. A. Strong: Summer diarrheas in infancy and early childhood, Arch. Pediat. 47:344-354, June, 1930.*

ated as the
y the carbohydrate. It
ally if given beyond 6
rhoea in many infants.
avoided and if it is de-
unt of carbohydrate, it is
actose by dextri-maltose
best to partly
and 2). In our view cane-
mixtures (Mead's Nos.
sugar is less suitable than lactose, and if for any
reason there is objection to the use of lactose,
is obtained by the addition of carbohydrates, while
fat and casein are reduced. For this purpose dex-
trimaltose and flour are better than the ordinary
sugars, since they are more slowly absorbed and
have greater efficacy in their powers of controlling
the flora in the large intestine."—*W. J. Pearson*
G. Wyllie: Recent Advances in Diseases
Blakiston's Son & Co., Phila., 1930.

For cases of fermentative diarrhea, ". . . the ideal plan of treatment would be to give a food which is low in sugar (the food which that group of organisms thrive on) and high in protein. Calcium caseinate milk accomplishes this purpose. In our series of cases, we found it was necessary to use the casein calcium for from 5-8 days; we then stopped it and added dextri-maltose to the formula."—*A. G. DeSanctis and L. V. Paider: The value of calcium caseinate milk in*
diarrhea, Arch. Pediat.

Just as DEXTRI-MALTOSE is a *carbohydrate* modifier of choice, so is CASEC (calcium caseinate) an accepted *protein* modifier. Casec is of special value for (1) colic and loose green stools in breast-fed infants, (2) fermentative diarrhea in bottle-fed infants, (3) prematures, (4) marasmus, (5) celiac disease.

Disinfection and Fumigation.—Disinfection and fumigation constitutes entirely different procedures which are used for entirely different purposes. Most people think of disinfection and fumigation as being identical or at least similar. Generally speaking, fumigation is designed to destroy insects, while disinfection is employed in the destruction of bacteria.

The first public health officer who recognized the inefficiency of fumigation in the destruction of harmful bacteria was Dr. Charles V. Chapin, superintendent of public health at Providence, Rhode Island. To this veteran official public health in the United States is indebted for many advances in the administration of public health, one of which is the removal of the unnecessary procedure of terminal fumigation following a communicable disease.

By no means should it be considered that fumigation is an unnecessary procedure altogether. It is most valuable in cleaning up premises that may be

For Acidity and Allied Conditions, we suggest ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

infested with insects, but it is of little, if any, value whatsoever in the destruction of agents that may cause infection.

Disinfection deals with the process of destroying the vitality of those minute organisms which may cause disease. In nature there are many forces that are destructive of such agents. Among them are sunlight, dryness, dilution and time. Perhaps the greatest destroyer of germ life is sunlight. Very few organisms can live in direct sunlight for many hours. Dryness is another factor of great importance in the destruction of such organisms. The combination of the two, together with simple cleanliness, constitute the most important attributes in the destruction of bacteria. The old idea that disease organisms are wafted about upon playful breezes is entirely dispelled. It is known that most of the bacteria harmful to man have their sources in man himself and after leaving their host,

ADVICE vs EXPERIENCE

OUR advice, based on the findings of Mulinos & Osborne, and Flinn,* in cases of congestion of some portion of the upper respiratory tract is to smoke Philip Morris.

But experience is the best teacher. Test Philip Morris on yourself. Test them on your patients suffering from irritation caused or aggravated by cigarette smoking. Your results too will show that Philip Morris in which only diethylene glycol is used as the hygroscopic agent are less irritating than those in which glycerine, the usual hygroscopic agent, is employed.

(Continued from Preceding Page)

unless they find favorable conditions for propagation and development, are short lived. For this reason terminal disinfection, which means disinfection after a case of communicable disease has been released from quarantine, has come to be regarded as of much less importance than concurrent disinfection, which means destruction of organisms immediately upon their discharge from their human host. Since man is the source of the infections to which he is heir, the best place to apply disinfection is at the source. Excretions from the nose, mouth and bowels, as well as discharges from wounds and eruptions upon the body surface, need immediate attention. When such procedure is followed there is little need for disinfecting the sick room when the illness has terminated.

Fumigation

Fumigation consists of liberating fumes or gases for the purpose of destroying vermin, insects and small animals which may act as carriers of infection. Fumigation, also, to a very limited extent may destroy bacteria organisms. The gases that are employed in fumigation are very often destructive to human life and extreme care is used in their employment. Fumigation never under any circumstances takes the place of disinfection. Gases always are most efficient in action upon surfaces, lacking power of penetration, and they can not be depended upon to penetrate fabrics or surfaces which may be absorbed in sputum or other discharges in which the disease organisms may be lodged.

In discussing the ideal disinfectant, Dr. M. J. Rosenau in his "Preventive Medicine and Hygiene" states: "The ideal disinfectant must, first and foremost, possess high germicidal power. It must not be rendered ineffective by the presence of organic matter; it must be reasonably stable so as not to deteriorate under ordinary conditions; it must be soluble or readily miscible in water; if it forms an emulsion

the emulsion should be permanent; it should be harmless to man and the higher animals; it should have the power of penetration; it should not corrode metals, bleach pigment, rot fabric or stain surfaces; and, finally, it should be reasonable in price." He adds further that it requires money and the expenditure of well directed and intelligent energy to accomplish satisfactory disinfection and that no one germicide is applicable to all diseases or to all substances or even to the same disease or the same substance under different conditions.

It will be seen that disinfection requires skill and knowledge and that in order to destroy disease organisms that may be associated with a case of illness the services of an individual who is a skilled disinfector are required. Merely to burn sulphur or other agents in a sickroom following a case of illness is comparable to "burning incense to the unknown gods."

The general public is often misinformed upon the difference between fumigation and disinfection, and health officers are frequently asked for advice upon proper methods of fumigation, when as a matter of fact disinfection is called for and not fumigation. It should be understood that both of the procedures are important in public health administration and neither should be neglected or abandoned. Each has a definite place among those procedures that have to do with the protection of the public health. The problem lies in giving proper information to the average individual so that he may easily understand the difference and the distinction.

Nothing is more important for many people to know than that heart disease does not kill people suddenly as a rule—these instances merely stand out as spectacular examples—most cases respond favorably to moderate living and justify an optimistic outlook on life. Rest, exercise, occupation, diet—all need attention and skilled regulation.

FOOD-DRINK ADDS AVAILABLE IRON TO THE DIET!

●

ALSO RICHLY PROVIDES CALCIUM, PHOSPHORUS AND VITAMIN D

COCOMALT, the delicious chocolate flavor food-drink, is a rich source of available Iron. An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form.

Thus three cups or glasses of Cocomalt a day supply 15 milligrams — which is the amount of Iron recognized as the normal daily requirement.

Used as a delicious food-drink, Cocomalt provides a simple, palatable means of furnishing Iron to growing children, convalescents, expectant and nursing mothers.

... and for bones and teeth

In addition to Iron, Cocomalt is rich in Vitamin D — containing at least 81 U.S.P. units per ounce. Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation.

Cocomalt also has a rich Calcium and Phosphorus content. Each cup or glass of this tempting food-drink provides .32 gram of Calcium and .28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth: Calcium, Phosphorus and Vitamin D.

Easily digested — quickly assimilated

Not the least of Cocomalt's many virtues as a food-drink is its *palatability*. It is so refreshing, so delicious, it appeals even to the very sick. And though it provides exceptionally high nutritional fortification, it is easily digested, quickly assimilated, imposes no digestive strain.

Recommended by you and taken regularly, Cocomalt will no doubt prove of great value to many of your patients.

FREE TO DOCTORS

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

Cocomalt
A DELICIOUS FOOD DRINK
CHOCOLATE FLAVOR

Cocomalt is the registered trade-mark of the R. B. Davis Co. Hoboken, New Jersey.

R. B. Davis Co., Dept. 19-H, Hoboken, N. J.

minimizes scarring

A FEATURE OF

ANTI-PYREXOL

This most comfortable, and least troublesome dressing for burns may be depended upon to:

1. Relieve pain promptly.
2. Protect denuded areas.
3. Give antiseptic protection.
4. Combat toxemia.
5. Promote prompt healing.
6. Minimize scarring.

Anti-Pyrexol is available through surgical supply houses and drug jobbers in 2-oz. tubes, 1-lb., 5-lb., 10-lb. tins. For technical information address Mona E. Bettin (M. D.), Pathological Laboratories, Roosevelt Building, Los Angeles, or:

J. L. ROBINSON, Inc.
Hilp Building Reno, Nevada

Violator of Federal Food and Drug Law Fined $4,000; Many Other Fines Assessed.—Shippers of dairy products, fish, nut meats, tomato products, fresh vegetables, macaroni and medicines were brought before the federal courts during June on a variety of charges, the current report of the Food and Drug Administration shows. Fines totaling $6,175 were assessed, with costs added in some instances.

Conspicuous among the cases terminated were those involving the shipment of canned fish found to be partially decomposed. The New England Fish Company, Seattle, Wash.; Klawock Packing Company, Klawock, Alaska; Deep Sea Salmon Company, Skowl Arm, Alaska, and the Wrangell Packing Company, Wrangell, Alaska, pleaded guilty to the shipment of partially decomposed canned salmon, and were fined $10, $10, $10 and $301, respectively. The Sea Pride Packing Corporation, Ltd., Terminal Island, Calif., was fined $200 on account of adulterated canned mackerel, and the French Sardine Company, same location, $500 because of adulterated canned mackerel and tuna. One other case based on the interstate shipment of canned fish (sardines) did not allege decomposition, but the substitution of sesame seed oil for the "pure olive oil" represented on the labels as the packing medium. The defendant, the Hovden Food Products Company, Monterey, Calif., was fined $150.

Ross & Co., Inc., LaBelle, Mo., shippers of cream found to be filthy, were fined $50 and costs in federal court at Hannibal, Mo. The prosecution, based on a shipment made during last year's intensive campaign for clean cream in buttermaking, is the first to terminate in that area. The defendant company had shipped sixty cans of cream, the contents of thirty-one of them being found dirty and decomposed. Through the coöperation of the State of Illinois, into which state the cream was shipped, seizure and destruction of the unfit cream was effected within two days from the time of shipment.

EVEN FOR SKIN STERILIZATION

● Where high sterilizing power is given first consideration—as for preoperative skin disinfection—Tincture Metaphen 1:200 recommends itself to the thoughtful physician. The drug Metaphen* itself is extremely powerful. The results of a study for the evaluation of Metaphen as a preoperative skin sterilizer and general antiseptic, reported in the Journal of the American Medical Association, Sept. 27, 1930, Vol. 95, pp. 917-923, show Metaphen to have a phenol coefficient of 1500 when staphylococcus aureus was used as the test organism; 900 on streptococcus hemolyticus; 750 on gonococcus; 571 on B. anthracis; 500 on B. subtilis and 250 on B. coli, the most resistant of all the test organisms. Metaphen does not coagulate tissue albumins, and is also non-irritating and non-poisonous in the dilutions recommended. Possessing these advantages, Tincture Metaphen (an alcohol-acetone-aqueous solution of Metaphen 1:200) is valuable for such exacting uses as those of preoperative skin sterilization; for dermatological practice and first-aid treatment. An orange stain defines the area to which the product is applied, but this stain may be washed from skin or dressings with soap and water.

TINCTURE METAPHEN

* The anhydride of 4-nitro-5-hydroxy-mercuri-orthocresol

Available everywhere in 1-oz., 4-oz., 1-pt. and 1-gal. bottles. Also available in untinted form. Up-to-date literature upon request. Use the coupon.

ABBOTT LABORATORIES, North Chicago, Illinois A-8-36

Please send me literature on TINCTURE METAPHEN and other Council-Accepted Metaphen Products.

THAT LIFE MAY BE PROLONGED

BLOOD CHOLESTEROL

In Diabetes

ABNORMALLY high blood cholesterol is characteristic of untreated and uncontrolled diabetes; and many now believe that the object of treatment should be not only normal blood sugar but normal blood cholesterol as well. Fatty infiltration of the liver, always undesirable, is particularly to be avoided in the diabetic. Recent work has suggested that a further increase in the carbohydrate and a corresponding decrease in the fat of the diet might aid both in lowering blood cholesterol and in preventing fatty infiltration of the liver.

'Iletin' (Insulin, Lilly) is supplied through the drug trade in 5-cc. and 10-cc. vials.

PROPOSED INITIATIVE LAW TO OPEN COUNTY HOSPITALS IN CALIFORNIA TO NON-INDIGENT PATIENTS WILL NOT BE ON THE STATE ELECTION BALLOT IN NOVEMBER

Petitions for the Proposed Initiative Lack the Necessary 186,000 Valid Signatures.—It is good news that current information brings to us,* namely, that the petitions for a proposed initiative law that would open the county hospitals of California to non-indigent patients failed of having the 186,000 valid signatures of voters, necessary to place the measure on the state ballot in November. California's legal requirements for placement of an initiative law on a state election ballot demand that the petition lists, gathered by notary public representatives and properly sworn to, must be filed with county clerks or county registrars of voters prior to July 15; these county officials then having until August 4 to check on the validity of the signatures, which on or before the latter date must be certified to the Secretary of State of California. Present advices indicate that the petitions will not be filed for the 1936 election.

* * *

The Theme and Summary of the Proposed Initiative.—CALIFORNIA AND WESTERN MEDICINE, in its issue for last May, on page 355 set forth the theme of the petitions and gave a summary of the proposed law as prepared by Attorney-General Webb; but for members of the Association who may not have read the same, these articles are here reprinted:

THEME OF PETITIONS

The petitions are addressed to the Secretary of State of California, and read:

> We, the undersigned, registered qualified electors of the State of California, residents of Kern County, present to the Secretary of State this petition and hereby propose an amendment to the Constitution of the State of California by adding Section 21 to Article XI thereof, to read as hereinafter set forth in full, and petition that the same be submitted to the electors of the State of California for

---

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

* See news items from Lodi *News-Sentinel*, and other articles printed in this issue on pages 207 and 211.

their adoption or rejection at the next succeeding general election or as provided by law.

The Attorney-General has summarized the proposed measure as follows:

> Establishment and maintenance of hospitals for pay patients by political subdivision. Initiative constitutional amendment. Authorizes the governing body of any city, county, or city and county, to establish and maintain a hospital for the care and treatment of any resident thereof, whether an indigent or non-indigent, and to enact rules prescribing the rates to be charged each resident, other than indigents, for hospital services and supplies.

* * *

Address of Alfred Siemon, Esq., Guest Speaker at the Coronado Annual Session.—In our comments in the May number, we made only brief mention of this proposed initiative. At the recent Coronado annual session, Alfred Siemon, Esq., of Bakersfield, who led the successful legal battle against the board of supervisors in the Kern County Hospital controversy, was invited, as a guest speaker, to address the House of Delegates on the subject of county hospitals, and in the course of his remarks stated:

"This proposed amendment is rather short, and I shall read it to you in full. As the petitions are being circulated it reads as follows:

> "'The governing body of any city, county, or city and county, is hereby authorized and empowered to establish and maintain therein a hospital or hospitals; to provide rules and regulations for the proper management and appointment of the necessary officers and employees thereof; and said governing bodies shall make rules and regulations governing the admission to and the care, as a patient in said hospital, of any citizen of the United States who is a resident of said county, city, or city and county, whether such persons be indigents or non-indigents, and may in said rules and regulations establish the rates or fees to be charged each non-indigent patient for services rendered and supplies furnished such non-indigent patient in such hospital.'"

* * *

For the Present, California Will Not Go into Private Hospital Business.—A perusal of the above reveals the far-reaching scope of this proposed law, which proponents in Kern and other counties felt certain they would be able to have the citizens of California enact through initiative vote. It is a hopeful sign, therefore, that in their preliminary efforts these propagandists were not successful, and it is our opinion that in the months ahead, before another state election is held in 1938, a full discussion of this contemplated law, which would make the constitutional political subdivisions of California, namely, its counties, engage in hospital business on a pay basis, in competition with the many hospitals that have been brought into being in the past, will result in the development of a strong sentiment among the voters and taxpayers of California, against any such extension of governmental function into a field where there is an imaginary, rather than a real need.

* * *

The Record of the Private Hospitals of California.—One has only to survey the California hospital statistics of recent years, and to consult the audits of income and expenses of hospitals, to be convinced that at the present time, and in most communities, ample hospital facilities exist, and that the charges rendered by these institutions are not out of proportion to the actual costs of the service demanded by patients. These hospitals pay taxes on their properties; their employees receive wages which rarely, if ever, are above the average; their costs for foods and supplies are held down to a minimum, and, be it said further, up to the present time, they have in good faith made it possible for the people of California to secure hospitalization facilities in keeping with the best standards in the United States. This proposed law would blot out most of these institutions through a competition whereby the non-taxed and politically-managed county hospitals would probably undersell the services of these previously-established institutions. In other words, this proposed law would practically make it possible for county boards of supervisors to use public funds to permit a limited number of citizens to buy hospitalization services at less than actual cost, and so engage in competition with private business. If this be permissible, why not then pass laws to permit boards of supervisors to maintain clothing and food establishments that could undersell those commodities, as quoted in the open market, to such citizens who felt they could not pay the prices in stores and shops, or who chose from the standpoint of personal economy, or chiseling, to avail themselves of such a privilege?

* * *

Proponents of the Initiative Seemingly-Blind to the Administrative and Other Difficulties.—Let it be remembered, too, that in all this discussion of hospital costs that has been presented by the proponents of this "county hospitals open to all citizens" measure, the advocates of the plan seem to have had no clear comprehension of the difficulties that would arise in hospital administration through admission and care in the same institution of non-pay (indigent) patients, side by side with whole or part-pay (non-indigent) patients.

Take, for example, the large Los Angeles County Hospital, whose most recent structural addition cost in excess of fifteen million dollars, and which constantly has between 2,400 and 3,000 in-patients. Even under present conditions, the problems which are constantly arising in the care of the several thousand indigent or charity patients are such as tax the best administrative supervision that can be had for that institution. If in that picture of some 3,000 patients, with its large administrative staff, fifty resident physicians, 125 internes, and 500 attending physicians, surgeons and specialists (this last group of attending men giving gratuitous service to the poor), one would bring into the institution through the proposed law, say, 1,000 or more pay patients with their personal physicians, many of whom would be unfamiliar with that hospital's routine, so necessary for efficient service, then it is possible to understand how, in a brief time period, one would have confusion ten times confounded. Think of the turmoil that would undoubtedly be created by pay patients who imagined they were entitled to better service than their indigent fellows! Would the pay patients be content to be cared for in the same wards with the indigents? Would they accept the same foods and service? And what would the board of supervisors do, in case an additional 1,000 pay patients demanded admission, when all beds were already filled? Which of the two types of patients, pay or nonpay, would be given preference under such conditions? Could not such pay citizens who were refused admission go into the courts with demands for damages? Would it then be necessary to build another fifteen-million-dollar unit for these pay or part-pay patients? And after that, then what?

* * *

Civic Obligations of Physicians in the Coming Primary and Final Elections.—One could go on and comment at length on some of the features of the proposed plan to "open county hospitals for all citizens," and emphasize not only the illegality but the impracticability of the entire dream. In good time, it may be necessary to do that very thing. For the present, we are content that the petitions for the new law are lacking in sufficient signatures, and we believe that among those to be congratulated are none other than the proponents of the measure, who evidently do not appreciate what they have been advocating.

On August 4, the newspapers will have informed us whether the petitions have been filed with the Secretary of State. Whether the proponents will use their present propaganda to influence the next California legislature, which will convene in January, 1937, we do not know. That is a something for future consideration. In that connection, however, we should all be alert to our immediate civic responsibilities, both in the primary election in August and, what is of equal importance, in coming to a decision as to what assemblymen and state senators will deserve support in the November elections. No legislator with unsound public health opinions should receive the endorsement of any physician or layman who believes in scientific medicine and proper conservation of the public health. Let us keep that fact in mind, and act accordingly.

DEL MONTE ANNUAL SESSION, MAY 2-5, 1937: PAPERS FOR SCIENTIFIC PROGRAM SHOULD BE STARTED NOW

Essayists for Next Year's Annual Session Should Write to Association Officers.—By the time this issue of California and Western Medicine reaches its readers, the Coronado annual session, the report of which was printed in our April number on page 301, will have been three months behind us, thus leaving only nine months for the preparation, by members of the California Medical Association, of papers that may be in contemplation for next year's annual session. Members having in mind such essays which they desire to submit for consideration by the various sections and the Committee on Scientific Program should communicate as soon as possible with the proper officials.

The roster of section officers is printed in each issue at the top of advertising page 4, and the names of the members of the standing Committee on Scientific Work are given under that heading on advertising page 2. Communications for that committee should be sent to Association Secretary Warnshuis, who is ex officio its chairman.

* * *

Rules Regarding Annual Session Papers Should Also Be Read.—The attention of members is also called to the "Rules Regarding Papers and Discussions at Annual Sessions," which will be found on page 315 of the April number. Observance of the simple and necessary requirements adopted by the Council will aid expeditious publication in California and Western Medicine, and make for the prevention of embarrassing situations that might otherwise arise. Authors should present original copies of their papers to their section secretaries at the time of reading; and section officers, in turn, will save themselves unnecessary correspondence and work in post-convention days by always asking for the original copies immediately after the papers have been read. Compliance with the above suggestions will make annual session programs convenient alike for authors, the section officers and Committee on Scientific Program, and for the Committee on Publications of the official journal.

HARRISON NARCOTIC LAW

Harrison Narcotic Law a Live Topic.—Discussions of the Harrison Narcotic Act in the medical press, from the time that law was enacted by Congress in the year 1914, have covered many, many pages. And rightly so, because repeatedly, in all sections of the country, federal officers, in their zealous efforts to enforce the statute, ofttimes have misconstrued their functions as laid down in the law, and thereby, through improper arrest, have subjected physicians to loss of both money and reputation.

* * *

Complications Arising from Operation of the Los Angeles Municipal Narcotic Clinic.—In Los Angeles several cases have been before the federal courts, in which members of the Los Angeles County Medical Association, who were on the staff of the municipal narcotic clinic—brought into existence and operated as one of the activities of the Los Angeles City Health Department!—were haled before the federal court charged with violation of the Harrison narcotic law.

* * *

Recent Decision of Federal Judge Leon R. Yankwich.—Under date of July 16, one of the physicians, so accused, wrote us the letter printed on page 213. He enclosed a copy of the opinion handed down on June 23, 1936, by U. S. District Judge Leon R. Yankwich.* To this decision, as sent out by the Los Angeles City Health Department, we are giving a place in the original articles department of this issue (so that it may more easily be tabulated in the index of medical literature), the subject being one which should interest all physicians. In connection with this presentation of the federal judge's opinion, it seems pertinent to republish the following editorial which appeared in CALIFORNIA AND WESTERN MEDICINE for January, 1926:

---

* See page 164 for full opinion.

NARCOTIC LAWS AND PHYSICIANS

National and state narcotic laws are being enforced with such superlative stupidity that the honest practice of honest scientific medicine by honest, adequately educated physicians is becoming increasingly more hazardous.

Medical opinion is practically unanimous in this conclusion, and what is more important, doctors everywhere are becoming restive under the autocratic rules of tax collectors as to what a doctor may do for his patients. The intelligent element of the voting public is securing some effective but tardy "education" which may in the course of time produce effective results.

Since the decision of the Supreme Court that our chief narcotic law is—as the doctors always have claimed it to be—purely a revenue measure, sane people in all walks of life are waking up to the surprising fact that we are trying to regulate a health problem by money-getting laws administered by money getters for moneyed reasons. People at last are beginning to realize, as one prominent non-medical citizen recently said, that our government is making huge profits out of a vice.

Laws, rules and regulations are now so numerous that an honest, conscientious doctor often must choose between his duty to his patient and the possible consequences of the law. This is to such an extent that many doctors refuse to take chances with tax collectors, undercover agents and what-not, by doing for sick people what scientific medicine endorses as the best treatment. Few doctors can carry in their minds the numerous things laws and painfully numerous bureaucratic regulations require of them every time they give or prescribe a dose of narcotic drugs.

One of the most illuminating analyses and digests we have seen of the Federal narcotic laws has been recently published—with their endorsement—by the Los Angeles County Medical Association. Every doctor ought to have a copy of this 45-page booklet on his desk, and he ought to study it. In order to pay part of the expense of publication, a price of 25 cents is charged, and the book may be obtained from the Los Angeles Medical Association.

* * *

It is suggested that members of the California Medical Association take the time to scan the opinion handed down by Judge Yankwich, because he clearly outlines legal limitations of this revenue measure. On the other hand, members of the Association are strongly advised to be meticulously careful in all diagnosis and treatment in which narcotic medication may be indicated, and especially so in the care of narcotic addicts.

FEDERAL SOCIAL SECURITY PROGRAM: SOME INTERESTING FACTS

For readers who may be interested in some of the facts and figures of the Federal Social Security Program, we have made the following compilation:

A Social Security survey was instituted in June, 1934.

Congress authorized the Social Security Program through a congressional act, dated August 14, 1935.

The Social Security Program operates under ten different titles or subdivisions.

The administration of the Social Security Program consists of two major parts:

One, a group of operating or line bureaus; and

Two, an administrative unit (comprising offices of the general counsel, bureaus of research and statistics, accounts and audits, public improvement and informational service).

The operating or line bureau comprising:

The Bureau of Old Age Benefits,

The Bureau of Public Assistance (which in turn includes state grants to needy aged, state grants to dependent children, and also state grants to the blind).

* * *

Congressional appropriations to carry out the immediate needs of the Social Security Act are:

For the fiscal year ending June 30, 1936, the sum of $42,500,000 was expended.

Available at the beginning of the present fiscal year (July 1, 1936) the sum of $475,253,410.

* * *

The Social Security Program provides funds for two types of activities: First, federal activities, pure and simple; and

Second, federal-state activities (the latter implying a coöperation of federal and state appropriations, through federal grants or allocations to states, given, however, only when certain requirements have been fulfilled).

* * *

Two of the Major Federal Plans:

1. *Federal Old Age Benefit System.* Pension or retirement system to persons past age 65, not engaged in gainful employment. This division will start payments in January, 1942, from funds collected as federal taxes in equal amounts from employers and employees. The taxation will start in 1937 at 1 per cent, in 1938 it will be 2 per cent, while in 1939 and thereafter the tax will be 3 per cent. The estimated income for 1935 is $568,400,000. In this program, farm-laborers and domestics are not included. It has been estimated that the federal old age benefit fund in forty years will have to its credit 50 billions of dollars!

2. *Federal Unemployment Compensation.* Here also a separate federal tax will be levied on all employers who employ eight or more persons. Employers will be taxed 1 per cent in 1936, 2 per cent in 1937 and 3 per cent in 1938 and thereafter. The estimated income for this fund in 1936 is $177,000,000, and for 1938, the sum of $530,000,000.

* * *

Federal-State Allocations:

The $187,000,000 allocated to the Social Security Bureau for specific activities during the present fiscal year is subdivided as follows:

(*a*) Federal grants to states for assistance to the needy aged, the sum of $85,000,000.

(*b*) Federal grants to states for aid to dependent children, the sum of $35,000,000.

(*c*) Federal grants to states to help the blind, the sum of $8,000,000.

Federal grants to states in many instances must be met dollar for dollar from state funds. (It is of interest to note that while the federal moneys must be handled through a state board, in nearly all instances a "lay advisory committee" is required, to supposedly aid in the distribution of the funds!)

The Federal Government, in making its grants or allocations of federal funds to California, will deal through the State Department of Public Welfare and the State Board of Public Health.

* * *

Federal Grants to States for Public Health Work:

A total of $8,000,000 has been set aside in the United States Treasury Department for allocations to states in aid of public health work, and an additional $1,320,000 has been set aside for public health research.

In such allocations or allotments, 57½ per cent of the federal appropriation must be met, dollar for dollar, by the respective states. Another 22½ per cent for aid in special health problems must also be matched by states, dollar for dollar. The remaining 20 per cent can be granted to states, as in the judgment of Public Health Service may be deemed best, it not being necessary to match dollar for dollar in funds from this last 20 per cent.

* * *

The Children's Bureau of the United States Department of Labor has had allocated to it for the present fiscal year $6,469,000, subdivided as follows:

Maternal and child-health services, the sum of $2,820,000;

For aid to crippled children, the sum of $2,150,000;

For child welfare services, the sum of $1,200,000.

The allotments for maternal and child-health services, and for aid to crippled children must be met dollar for dollar by the states, but the allocations for child welfare work need not be so matched.

* * *

We give the above figures in the form presented, because these activities are closely related to conditions having an intimate connection with medical practice. Members of the medical profession, therefore, should be somewhat familiar with these facts because of their possible ultimate influence on medical practice in the days to come.

RATIONAL OR NON-SECTARIAN MEDICINE: DR. WIDNEY'S ANALYSIS OF SECTARIAN MEDICINE, MADE FIFTY YEARS AGO, STILL APPLIES IN CALIFORNIA

Despite the Advances in Scientific and Rational Medicine, Sectarian Healing Art Groups Have Increased During the Last Half Century.—In the April and May issues* of California and Western Medicine appeared a sketch of exceptional interest outlining the life and accomplishments of Dr. Joseph P. Widney, founder of the Los Angeles County Medical Association; and to add to this valuable chapter in biography, in the June and July numbers was printed an address on "Rational or Liberal Medicine" which he gave some fifty years ago in Los Angeles. Members of the California Medical Association who failed to read these articles denied themselves a rare intellectual and inspirational treat.

At this time we wish to refer particularly to this paper, on a subject we are more prone nowadays to speak of as "Non-Sectarian Medicine," this latter term probably having come into being because of the increasing number of "schools" or "sects" of the healing art, whose propaganda has been sufficiently well conducted, not only to confuse the minds of the laity, but, in addition, to secure for such sects legal recognition in many states.

* * *

California a State with Multiple Healing Art Boards.—California is one of the commonwealths that is afflicted with such multiple healing-art boards, for in California we have a Medical Board, an Osteopathic Board and a Chiropractic Board. These two groups of healing-art sectarians were not only successful in securing initiative laws to establish their separate boards—equivalent to constitutional amendments—but the osteopathic group even went farther, by incorporating a flexibility to their initiative act, making it possible to secure, through legislative amendments to our own medical practice act, changes especially applicable to themselves! The chiropractors, being less alert, now have what might be called an initiative law so frozen that, whether they do or not desire it, they must recognize the graduates of all incorporated chiropractic schools, no matter how lax the standards in some of their teaching institutions may be!

* * *

How One of the Initiatives Prevents Desirable Amendments to the Medical Practice Act.—The osteopathic provisions which make it possible for that sect to secure changes by amendments to the state medical practice act would permit that group to raise its legal scholastic standards if it so wished. Unfortunately, it also permits that sect to interpose and object to amendments designed to promote or advance the standards for medical graduates; as witness, for example, our experience of several years ago, when an amendment we submitted to the legislature making obligatory a year of interneship as a preliminary requirement to taking the medical board examination failed of passage. On that occasion, the osteopathic group was able to influence a sufficient number of assemblymen and senators to prevent us from securing this much-desired amendment to our own medical practice act! Strange as it may seem, that is the fact!

In California, therefore, we have, first, a medical practice law, enacted by the state legislature; second, a chiropractic law passed by initiative vote of the people, and so frozen in part that only by initiative vote of the citizens can it be amended—a process so expensive as to almost be prohibitive; and, third, an osteopathic practice act also brought into being by initiative vote of the people, but containing a clever provision permitting it to be amended as to standards, through amendments of our own medical practice act which, as already pointed out, may make it difficult for physicians and surgeons to secure amendments applicable to their own schools and graduates unless the same be also acceptable to the osteopaths!

Printed Announcements of Sectarian Healing Art Schools.—It is not our purpose here to discuss the curricula of the various sectarian healing art schools. These, insofar as printed catalogue expression is concerned, are usually gloriously outlined in announcements, with generous allocations of "hours" to all subjects, from which it is necessary, if one would be properly oriented, to read not only the lines, but between, and also, to confirm mere impressions by personal investigation of the physical and scholastic equipments of the institutions, in order to prove whether these are in harmony with the printed statements.

Doctor Widney's Able Analysis of Non-Sectarian and Sectarian Medicine. — Which brings us back to our initial reference to Doctor Widney's address of half-century ago, wherein he so ably stated the cause of Rational or Liberal (Non-Sectarian) Medicine, at a time when the homeopathic and eclectic schools were the only prominent exponents of sectarian medicine. From Doctor Widney's paper we quote and commend for perusal the following illuminating paragraphs, as true today as when they were spoken some five decades ago:

RELATION OF RATIONAL OR LIBERAL MEDICINE TO THE VARIOUS SCHOOLS OF MEDICINE

By bearing in mind what rational or liberal medicine is aiming at in its own development, it is easy to infer what must be its relationship toward the various schools, or systems of medicine, which from time to time spring up. It is itself aiming at freedom from dogmas, for these inevitably lead, as it has too often discovered in its own history, to narrow and one-sided generalization.

It has in all these ages of seeking after truth so often felt the evil of such things that it has learned to beware of them. It therefore says to schools or systems basing themselves upon fixed dogmas:

These things belong to the past: modern science has grown beyond them. Such dogmas imply narrowness. It is a step back toward the dark ages again. Only the broadest freedom of investigation should be recognized in scientific research. Because you have thus abandoned the broader field, and have restricted your research to the narrow limits of a fixed and unchangeable creed, we can not accord to you full recognition as broad and progressive members of a liberal profession. Science knows no boundary lines of creeds; and in the ranks of scientists the days for shibboleths have gone by. It is *because* you have abandoned the broader field of rational medicine, and *because* you are hydropathic physicians, or eclectic physicians, or homeopathic physicians—men whose science is bound up by a preconceived and inflexible theory, and because you are not simply *physicians*, men free to seek for, and to use, truth wherever found, that you are not accorded recognition as worthy representatives of a liberal and rational medicine. It is because you load yourselves down with clogs in the shape of *pathies*, and tie the load on by a distinctive name. Liberal medicine refuses to so encumber itself with clogs: ties itself to no set theories: binds itself by no name distinctive of a fixed creed: and so has to unload itself of no fixed burden of clogs when it would advance.

To the individual members of these schools Liberal Medicine says: Recognition is not withheld from you because you, as individuals, hold some theories of disease and of treatment which we consider narrow and ill-founded, for many individual men within the ranks of liberal medicine hold opinions probably deemed by their fellows equally odd, and yet are simply looked upon with a lenient smile as men who have some queer fancies; but it is because you elevate the fancy into a dogma, and build thereon a sect, and tie yourselves to it, making it a restrictive creed for education, and a test of standing. It is not because you, as individuals, are considered to hold only a partial truth, for many within the ranks of regular medicine fail to grasp the breadth of its teachings, and all their days are only as lame men in the pathway, but because you insist that this is all of truth and restrict yourselves to it.

Liberal medicine has tenets and treatments which resemble from one point of view homeopathy, others which resemble hydropathy; but it recognizes the fact that these are only partial and incomplete views, and are not all, but that more lies beyond. It lifts its eyes from the single hills toward the eternal highlands which it knows must tower through the mists above and afar. It may as yet catch only partial glimpses of that higher ground of medical science, but it feels that somewhere, on through the mists, it lies; and will be content with no resting place that is short of that goal. And it may be that the limits placed upon human knowledge by human weakness make the goal an unattainable one. Still it will climb the higher by being content with nothing less.

Another reason why the profession of liberal medicine has declined to accord recognition to these various schools and systems, is the character of the educational work which they permit within their ranks.

The constant struggle of rational medicine is to raise the standard of education. Under this endeavor the standard has been raised, as has already been stated, from the old-time country reading and a certificate, or possibly a single course of lectures, to a three years' graded course, with clinical work in the hospitals, and rigid examinations. And the tendency is toward a still higher standard. It is not unfair to say that this effort to raise the standard of education upon the part of liberal medicine has not been met by a corresponding effort among the schools or systems enumerated. While there have been some honorable exceptions, the general standard has been low, and without a well-expressed desire or intention of a change. It is no unfair or unjust rule which rational medicine applies to these schools, for it applies the same test to itself. The so-called college of rational medicine which does not conform to the requirements of the higher education, or which lowers its grade, at once loses caste, and is refused recognition. And this is the point in which those of the schools in these systems, which attempt the higher education, fail of reaping the just fruits of their more honorable work. For instead of declining to recognize the colleges which cling to the inferior standard of education, they continue to recognize them as legitimate institutions of learning, and admit their defectively educated graduates to an equal standing with their own who have honestly done better work. In this way they practically neutralize the effect of their efforts to elevate the standard of their colleges. . . .

AND THE QUESTION OF SCHOOLS? OF DOGMAS? OF THEORIES?—WHAT OF THESE?

Time will settle these: time, and more knowledge. As I have already said, one of the merits of rational medicine of today is, that it has learned to beware of positive dogmas and theories, and the schools which are based exclusively upon them. It has found that they are short-lived, and die out; for they are based not upon science, but upon one view of science. Then, if that view proves to be narrow, or mistaken, or false, there is nothing left, and of course they die. It has felt in its own history the evil of these things, and how they may become a clog and a bar to progress. It has learned that even today, with all the great advance which has been made in the accumulation and classification of facts, the stock is not yet sufficient for final generalization; and so has learned to work and to wait. In so varied a field, with a causation so varied, will a single general theory of disease, its causation and its management, ever be possible? It may be doubted. It certainly is not as yet. And so rational medicine, grown wiser than of old, aims to waste no time, no labor, upon problems which are as yet of necessity unsolvable. Instead, its aim now is to delve yet more deeply into the facts, and to push ever higher the standard of medical eduction. It feels that by this road, and by this road only, is the way to the higher truth. . . .

And the time will come, in that newer day, upon that higher plane of science, when schools will drop away; and no one shall say "I am of Paul, and I of Apollos," but the science of medicine shall be one: the doctor shall become doctissimus, and he shall be only a *physician*, a healer of men.

CONSTITUTION AND BY-LAWS OF THE CALIFORNIA MEDICAL ASSOCIATION: A NEW AND REVISED EDITION

At Coronado, the Council instructed the Secretary and Editor to prepare a revised edition of the Constitution and By-Laws; and to incorporate therein the amendments adopted since the San

Diego annual session of 1929, at which time the present-day rules, after considerable discussion at four previous annual sessions, were unanimously adopted. For the purpose of permanent record this revised edition is printed on page 184 of this number of CALIFORNIA AND WESTERN MEDICINE.

Reprints, however, will be made and a copy sent to every member of the California Medical Association, space being reserved in which additional amendments may be inserted. In this revised edition, key numbers are used in those sections that have been amended. These key numbers can be continued and used also for amendments that may be adopted in the coming years, thus making possible an up-to-date edition for all who wish such. Members may well take the time to glance over the text of the Constitution and By-Laws of the Association, because the code as it now exists outlines a system of government that is both representative and centralized and yet elastic and responsive to the will of the organization.

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 179.

EDITORIAL COMMENT†

RETICULOCYTES: THEIR COLOR, VOLUME, AND SATURATION INDICES*

While examining the literature on the changes in the red blood cells during the course of various types of anemias, it became apparent that if the changes in these measurements were correlated not only with the condition of the subject, but also with an index of immaturity of the blood, we could obtain further information on the characteristics of the immature red cell. The volume, color, and saturation indices, as of Haden,[1,2] (a relative measure of the volume of the red cells, of the amount and of the concentration of hemoglobin in the cells) have been employed extensively in the clinical diagnosis of the various types of anemias. They have also been used in measuring the changes in the characteristics of the red cell during anemia in experimental animals. Several authors have published data on these measurements, and at the same time have given reticulocyte or differential red-cell count. Although the crude data are given, the authors have not analyzed them with respect to the relation between the blood picture and the above cell characteristics.

In order that we may study the changes taking place in the red cell during maturation, it would seem advisable to correlate the characteristic of a blood sample with an index of immaturity of that sample. The per cent reticulocytes, per cent basophils, or other types of count for immature red cells, may be taken as an index of immaturity of a blood sample.

Using the data submitted by Kindred and Corey[3] (Table 2) and Smith[4] (Table 2) on rats, and Camero and Krumbhaar[5] (Table 2) on dogs, the coefficients of correlation between an index of immaturity of the cell sample and the characteristic of the red cells in question have been calculated. Other authors have published the same type of data, but the numbers involved were not adequate to be analyzed in this manner.

The coefficients of correlation and their probable errors are as follows:

Color index versus per cent eosinophil red cells (Kindred and Corey[3]), — .470, ± .055.

Color index versus per cent reticulocytes (Smith[4]), + .816, ± .033.

Color index versus per cent reticulocytes (Camero and Krumbhaar[5]), + .348, ± .062.

Volume index versus per cent reticulocytes (Camero and Krumbhaar[5]), + .350, ± .066.

Mean diameter versus per cent reticulocytes (Smith[4]), + .792, ± .037.

Saturation index versus per cent reticulocytes (Camero and Krumbhaar[5]), — .451, ± .067.

These coefficients of correlation are all significant and indicate that:

1. The amount of hemoglobin which is contained in the mammalian red cell (rat and dog) is greater in samples of blood containing higher proportions of immature red cells. This in turn indicates that, as the red cell becomes more mature, the actual amount of hemoglobin contained in it becomes less. Three separate sets of data are presented to support this thesis. Two of them are based on the reticulocyte count, while the third is based on the eosinophil red-cell count.

2. The mean volume and diameter of the red cell are larger in the blood samples containing a higher proportion of immature cells than in samples containing a low proportion of immature cells. Hence the immature red cell found in the circulation is larger than the mature cell and gradually decreases in size.

3. The concentration of the hemoglobin in the red cell increases as the per cent of reticulocytes decreases, indicating that the concentration of the hemoglobin in the maturing red cell increases even though the total amount decreases.

COLLAPSE THERAPY IN PULMONARY TUBERCULOSIS*

By J. J. Singer, M.D.
St. Louis, Missouri

Tuberculosis of the lungs is still one of the most common causes of death, especially between the ages of twenty and forty. These years are the most productive and creative periods in our lives, and therefore even greater efforts should be made to lessen this terrible toll.

Until rather recently the best known method in treating pulmonary tuberculosis has been rest, either at home or sanatorium. The problem was whether the patient could afford proper treatment and what would become of his dependents. Many organizations sprang up throughout the country, such as tuberculosis associations, clinics and social service groups, to educate the public by pamphlets, radio talks, lectures, etc. Cities, counties and states soon founded sanatoria to take care of indigent tuberculosis patients and the social group took care of the families.

After a trial of many years of rest under these arrangements, often with the best possible medical care, statistics did not show a materially lower death rate.

Recognizing this situation, attempts to alter these conditions were made by phthisiologists, with the aid of surgical colleagues, newer methods of treatment were tried, and thus compression therapy was born. These methods are as follows:

1. Artificial pneumothorax
2. Internal pneumolysis
3. Oleothorax
4. Phrenicectomy
5. External pneumolysis
6. Apicolysis
7. Partial and complete thoracoplasty

PNEUMOTHORAX

James Carson,[1] of Liverpool, in 1820 first suggested pneumothorax, but no attention was given to the suggestion until Forlanini of Italy and later Murphy of Chicago again suggested pneumothorax treatment in tuberculosis. It was Brauer of Hamburg who really popularized this method.

Clive Rivière stated that pneumothorax treatment was the brightest ray of sunshine in the dark history of tuberculosis. From the beginning of its use, the most dramatic cures were noted; so much so that this form of compression therapy was used widely, but not too well; and as the result of the unsuitable cases, this method was soon in disrepute.

Instruments were developed and with the advent of the use of the manometer to measure pleural pressures, the pneumothorax treatment was put on a scientific basis. Results in tuberculosis changed for the better.

TECHNIQUE OF PNEUMOTHORAX

The technique of performing pneumothorax[2] treatment at the Medical and Surgical Chest Service of the Barnes Hospital, St. Louis, is as follows: The patient is first fluoroscoped in the upright position, and then lying with the affected side up, the skin is swabbed with tincture of iodin and washed off with alcohol. A small sterile sheet, which has a small circular opening in it, is draped over the patient in such a manner that the prepared area of skin can be reached through the opening. With a small needle and a hypodermic syringe, 2 or 3 cubic centimeters of 0.5 per cent novocain are injected into (not under) the skin to produce an elevated white wheal. A stab incision through the skin of the wheal is made with a sharp cataract knife and through that opening a long, fine needle is inserted to inject novocain into the deeper tissues of the chest wall, including the pleura.

When the local anesthesia is completed, a needle about 3½ inches long with a fairly large bore is connected to a sterile rubber tube, which in turn is connected to a sterile glass tube containing sterile cotton. The needle and attachments are connected to the pneumothorax apparatus ready for introduction of air into the pleural cavity. When the needle is in the pleural cavity, the manometer will register varying degrees of negative or positive pressure, depending on the phase of respiration. In most cases under treatment one finds a negative pressure on inspiration varying from —12 to —18, and on expiration of from 0 to —8. One should not begin the introduction of air into the pleural cavity unless the manometer readings show that the needle is in the free pleural space. If one should obtain either no reading at all or evidence of a positive pressure, it is best to find another site, since such findings often indicate that the needle has been inserted into a mass of adhesions rather than into the free pleural cavity.

When a negative pressure is obtained we allow air to enter the pleural cavity, but not more than 200 cubic centimeters at the first injection. The patient is then examined immediately with the fluoroscope in the same position as that used for the injection of the air, because in this position (horizontal, with the affected side uppermost) the pneumothorax is best visualized. If the patient is then placed in the upright position before the fluoroscopic screen, the air in the pneumothorax pocket will now be seen in the upper portion of the chest. In this way one can determine not only if adhesions are present, but also whether they are narrow or broad bands. One can also usually determine easily if the lung is actually partially collapsed or if, instead, it is pushed over somewhat into the other side of the thorax. This condition may exist even in the presence of a negative pleural pressure if the mediastinal partition is sufficiently mobile. Statistics gathered by Rist and many others, including ourselves, follow (Table 1):

Guest-speaker address read before the first general meeting of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

TABLE 1.—*Percentage of Results in 759 Cases of Artificial Pneumothorax (Rist [3])*

		Per Cent	
Healed	51	6.5	
Clinically well, symptom free, working, but still under treatment	336	45.5	52 per cent
Condition unchanged	33	4.0	
Bilateral (alive)	99	13.4	48 per cent
Deceased	240	30.5	
	759	100	100 per cent

Condition of Controls (Adhesions) (Rist)

Able to work	8	8.5	
Living in institutions (unable to work, condition unchanged or worse)	35	37.2	91.4 per cent
Deceased	51	54.2	

The Medical and Surgical Chest Service, Barnes Hospital Statistics:

84 of our cases
13—17 per cent clinically cured
7— 9 per cent still taking pneumothorax
10—13 per cent definitely improved
16—21 per cent moderately improved
12—15 per cent slightly improved
5— 6 per cent not improved
13—17 per cent dead
8—not known

(Other statistics show similar results.)

A NEW SIMPLE PNEUMOTHORAX APPARATUS

I have recently devised a new small pneumothorax apparatus * which weighs approximately five pounds. No fluid is used in any of the parts. It consists essentially of 100 cubic centimeters air reservoir, an air manometer with jewel movements which registers the negative pressure —30 and the positive +30, and a commutator valve. This valve, by suitable movements of the handle, connects with the air reservoir, with the manometer, and with the chest cavity. By means of this apparatus one can permit 100 cubic centimeters of air to enter the pleural cavity at a time, and pleural readings are taken; and then another 100 cubic centimeters of air is injected until the proper manometer readings are obtained. By referring to the photograph of the instrument, one can readily see the simplicity of the machine.

INTERNAL PNEUMOLYSIS

Unfortunately, many cases of tuberculosis are not benefited even by pneumothorax treatment, due in many instances to dense adhesions between the parietal and visceral pleura. Jacobaeus,[1] of Sweden, was the first to sever these adhesions through an instrument called a thoracoscope. The patient is prepared, as for a pneumothorax; and while under twilight sleep anesthesia and local anesthesia, the trocar is introduced into the pneumothorax cavity. The trocar is removed and an electric-lighted tube (thoracoscope) is introduced with proper eyepiece. One can see into the cavity and note whether adhesions are too thick to burn with a cautery. Two methods are used, one puncture or two punctures. The first method is sim-

TABLE 2.—*Intrapleural Pneumolysis. Remote End-results of Operation, 206 Cases*

Result of Operation	No. of Cases	Condition Before Operation				Present Condition					Remarks

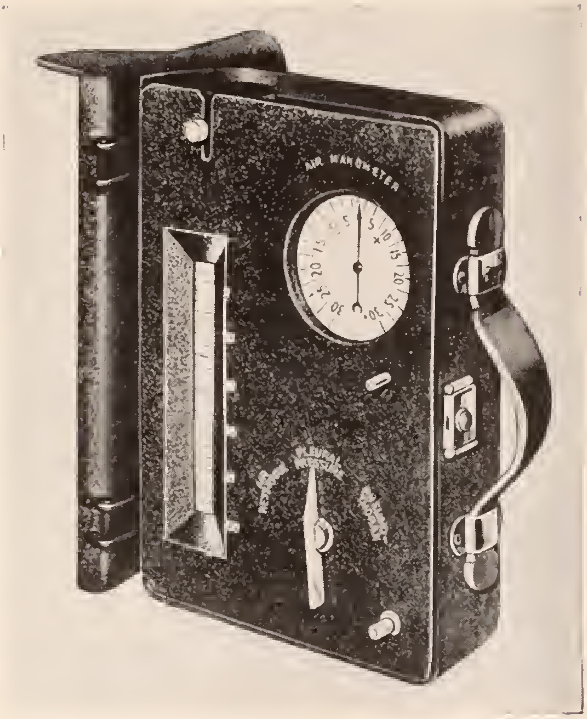

Fig. 1.—The author's new simple portable pneumothorax apparatus. See text for description.

pler, but the field of vision is slightly less than in the latter. At times the single puncture method is not effective on account of the position of the adhesions.

By this method many cavities, which were held open by the adhesions, collapse when they are cut and then ordinary pneumothorax is continued.

This operation, when successful, may save many patients a later thoracoplasty; therefore it is worth while attempting. It requires considerable experience to perform this operation, however, and there are relatively few men as yet who are sufficiently trained to do this.

Ralph Matson[5] reports results with internal pneumolysis as shown in Table 2.

OLEOTHORAX

In 1922 Bernou,[6] of France, proposed the use of massive quantities of antiseptic oil whether mineral or vegetable, in supplanting an unsatisfactory pneumothorax, and has used this method in selected cases and obtained excellent results. Ralph Matson has described oleothorax in several interesting articles.

The antiseptic quality of the oil tends to prevent the formation of empyema, and also obviates the necessity for frequent refills. The oil remains almost indefinitely and it is rarely necessary to aspirate the oil.

The method of administration is not difficult. At the first injection only about three cubic centimeters of the oil is used, with one to ten per cent gomenol, to test the tolerance of the pleura. Later, more oil is injected and the pneumothorax, which was present, is lessened by aspiration of air and replacement by the oil. Later refills and aspiration of air, 200 cubic centimeters at a time, the frequence of refills depends on the reaction.

Ray Matson[7-2] recorded a series of 100 cases subjected to oleothorax treatment during the past seven years, wherein the period of observation was long enough to justify reliable conclusions.

Disinfection oleothorax, alone or combined with an inhibition or compression oleothorax—50 cases. Satisfactory results were obtained in 60 per cent, that is, the empyema was cleared up and the collapse was maintained. The results were unsatisfactory in twenty cases (40 per cent). Causes of failure in these cases were: pleuro-cutaneous fistula, four cases; pleuropulmonary fistula, four cases. The object of the oleothorax—that is, disinfection of the pleural cavity—failed in eight cases. Reformation of the purulent exudate, necessitating abandonment of treatment, occurred in four cases.

Inhibition and compression oleothorax—fifty cases. Satisfactory results were obtained in twenty-five cases (50 per cent). Unsatisfactory results —twenty-five cases (50 per cent). The treatment was temporarily abandoned, but successfully reestablished in fifteen cases (30 per cent). The treatment was permanently abandoned in twenty-five cases (50 per cent). Abandonment of treatment in the above cases was necessitated in twenty cases, because of a persistent exudate formation. In five cases the treatment was abandoned because of severe constitutional reactions.

PHRENICECTOMY

The purpose of the operation on the phrenic nerve is to paralyze the corresponding half of the diaphragm. There can be little doubt that phrenicectomy has failed to justify the expectations of many. It is believed that the procedure has found favor largely because of the simplicity of the operation. Careful analyses of the postoperative results, as reported by men of various countries, have shown that phrenicectomy has a definite place in the treatment of pulmonary tuberculosis. The best results have been obtained when the lesion is in the lower lobe. The pneumothorax is usually attempted first, however, and when this is unsuccessful, then the phrenicectomy operation is considered. Occasionally adhesions prevent a good collapse in pneumothorax; these adhesions also operate to prevent the best results in phrenicectomy. We have noted that, although the diaphragm does not rise high in the chest, the fact that muscles are paralyzed on that side permits compression from the opposite lung to be transmitted through the abdomen upwards on the operated side.

It was first suggested by Sauerbruch[8] that a preliminary phrenicectomy should be performed routinely before every thoracoplasty. He stated that if no reaction followed, such as fever, sweats, and increase of the tuberculous process in the lungs, then the patient could stand a thoracoplasty. In incomplete pneumothorax, a phrenicectomy will keep the lung in better collapse if the diaphragm is paralyzed. Occasionally we have patients who have a reaction following the pneumothorax; and if this continues it has been our custom to do a phrenicectomy on that side and discontinue the pneumothorax treatment. Before completion of the pneumothorax treatment, temporary paralysis (phrenic crush) will keep the collapse of the lung for a period of three to six months. The final cure of tuberculosis by phrenicectomy has been somewhat of a failure. On only 4 per cent of our patients upon whom the procedure was used did we have what we could call a cure.

TECHNIQUE, PHRENIC CRUSHING, PHRENICECTOMY AND PHRENICOTOMY

One may perform either permanent or temporary interruption of the phrenic nerve. Local anesthesia or nitrous-oxide-oxygen may be used. A small sand-bag is usually placed between the shoulder blades and the head is turned sharply to the contra lateral side of the operative site. The incision is made about one inch (three cubic centimeters) above the clavicle, and need not be more than one or two inches in length. After the skin and platysma are divided, the sterno-cleido-mastoid muscle is split longitudinally immediately over the scalenus anticus muscle. The landmark which is constantly sought is the scalenus anticus muscle because this muscle is crossed on its anterior surface by the phrenic nerve from without inward. The phrenic nerve is the only one which follows this course. The nerve is picked up with a hook, and if the operation of exeresis is to be carried out, it is clamped, cut and the lower end twisted out of its bed slowly. In the case of a phrenic exeresis it is usually desirable to obtain twelve to fifteen centimeters of the nerve. One may feel reasonably certain that connections with the accessory phrenic nerve have been broken.

In the case of a simple phrenicectomy, the nerve is merely cut across. For temporary phrenic interruption the usual procedures are simple crushing of the nerve with hemostatic forceps. After crushing, the nerve regenerates with return of function of the diaphragm in from three to six months.

EXTERNAL PNEUMOLYSIS

External pneumolysis is the operation of opening the chest cavity by incision of skin, muscles, and separating the ribs by instruments cutting the pleura and directly severing adhesions, either by cautery or knife, between forceps. This method is not used often, as empyema is a more common complication and thoracoplasty becomes necessary.

EXTRAPLEURAL PNEUMOLYSIS

The term extrapleural pneumolysis implies separation of the lung with its adherent parietal and visceral pleura in toto or in part from the chest wall. The term apicolysis implies separation of the apex of the lung from the chest wall.

Schlange,[9] Sauerbruch,[8] E. A. Graham [10] and others have employed gauze-packs to obtain compression. Rubber balloons have also been employed. Pneumolysis and apicolysis have been performed as independent procedures. When performed at the same time as the thoracoplasty, the results may be more striking, but there is then considerable hazard.

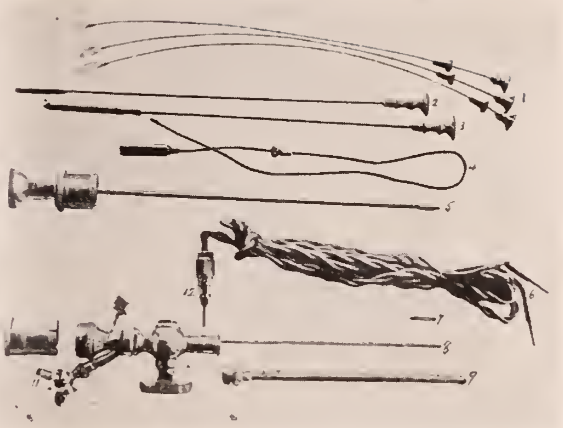

Fig. 2.—Thoracoscope for single puncture operation. (Devised by the author.)

Extrapleural pneumolysis has been carried out through axillary incisions, anterior incision or through a paravertebral incision. Many prefer the anterior approach. The operation requires the resection of a portion of at least one rib. Separation must be done with care and all bleeding controlled. During the separation the pressure is exerted in the direction of the chest wall rather than against the pleura and lung.

PLOMBAGE

Baeir [11] (1913) recommended the use of a mixture which contained a substance opaque to the Roentgen ray. He employed paraffin which had a melting point of 58 degrees Centigrade, in combination with paraffin which had a melting point of 50 degrees Centigrade. He used 75 cubic centimeters of the former and 25 cubic centimeters of the latter. To this mixture he added 1 gram of bismuth carbonate and 0.05 gram of vioform. Nisson [13] prepares the mass for plombage in the following manner: 75 cubic centimeters of paraffin with a melting point of 58 degrees Centigrade are melted with 25 cubic centimeters of paraffin with a melting point of 43 degrees Centigrade to 44 degrees Centigrade. One cubic centimeter of bismuth carbonate and 0.05 cubic centimeters of vioform are added to a small amount of this mixture. A uniform mixture is obtained by stirring for one-half hour and gradually adding the rest of the paraffin to the small mixture which contained the vioform. The mass is then placed in glass vessels with tight covers and is sterilized in a vapor sterilizer on two successive days for one hour on each occasion. The vessels are heated in a water bath and shaken to make the mixture uniform just before using. The liquid is then poured into a sterile porcelain dish and allowed to cool until it is of a homogenous consistency, pale yellow in color, and readily kneadable. From 500 to 600 cubic centimeters of this mixture is safe for most compressions. More than this amount may produce sufficient pressure to erode into the cavity with disastrous results. At body temperature, this paraffin becomes rather firm, and remains so, but occasionally some of the mass breaks off

and erodes into a bronchus and may produce bronchial pneumonia. This is one of the dangers of plombage.

The advantages of plombage are its simplicity, because it avoids extensive operations, and results are immediate. The method can be used in bilateral lesions in patients who need a thoracoplasty, but who are physically unable to stand this type of operation.

The operation consists of resection of about three centimeters of the third or fourth rib, posteriorly. The finger is inserted through this opening, and with a stripping motion the lung is separated without rupturing the pleura. By referring to the illustration (Fig. 4), one can readily see how the cavity is manually compressed and the space which is made by finger dissection is filled with the prepared paraffin. Baeir, Nisson and Winternitz have all reported excellent results. It has been our custom not to use the paraffin pack if thoracoplasty could be done.

Bilateral involvement does not contraindicate plombage. Extensive cavitation on one side, with no evidence of fibrosis or fixation of the mediastinum, is also an indication if pneumothorax is impossible because of adhesions. Plombage may be used to prepare the mediastinum and to create adhesions, and also to supplement the incomplete collapse of a cavity by thoracoplasty.

Plombage may, of course, be carried out on both sides, since it does not put the entire lung out of function. Complete obliteration of the pleural space is even more necessary for plombage than for thoracoplasty. It is advisable to do a diagnostic pneumothorax before operation in order to determine whether or not the pleural space is free.

The operation consists of resection of about three centimeters of the third or fourth rib, posteriorly, subperiosteally through a paravertebral incision. The pleura and lung are separated from the chest wall in the manner usually employed in carrying out an external pneumolysis. As one might expect, the postoperative reaction is similar to that following any compression therapy, and is in the form of a "tuberculin" reaction. Postoperative fever may be due to the formation of an exudate around the paraffin. The exudate should be aspirated whenever necessary.

Winternitz of Hungary reported excellent results in thirty-six cases, with definite improvement in twenty-eight.

EXTRAPLEURAL THORACOPLASTY

Rest is still of fundamental importance in the treatment of pulmonary tuberculosis. General body rest is no less important than rest of the diseased part. Thoracoplasty contributes to the local rest and is, therefore, not to be considered as a substitute for the general body rest, which must be carried on after thoracoplasty. Those patients who have already demonstrated the ability to help themselves are the ones who are most benefited by this operation, because they have shown a resistance to the disease. The most satisfactory evidence of this natural resistance in most cases is presented by the clinical course of the disease and the Roentgen findings. A displaced trachea to the affected side, narrowed intercostal spaces and elevated diaphragm are all definite evidence of resistance on the part of the patient. Other manifestations of resistance are the absence of active tuberculosis involvement in other regions in the body, and the lack of positive physical signs in the so-called good side. Sometimes the x-ray and physical signs of a naturally collapsed lung due to fibrosis, are misleading. By bronchography,[12] with iodized oil, one can see the true character of the lung cavities, and bronchiectases are noted. These cavities naturally prevent the lung from healing, and thoracoplasty in this type of case frequently permits the cavity to be healed.

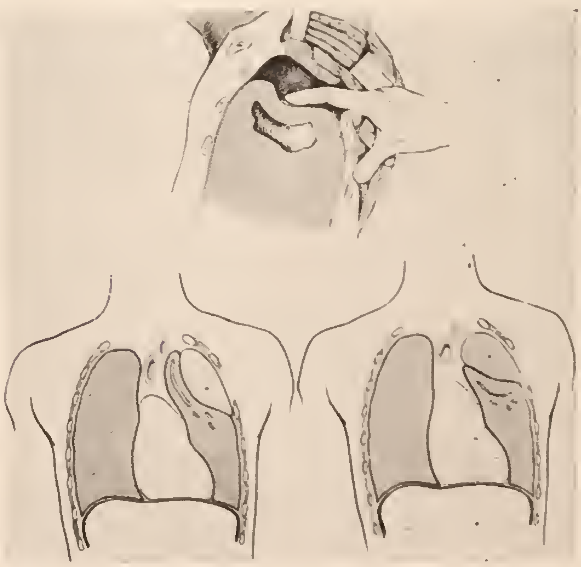

Fig. 4.—Technique and end results following plombage for a tuberculous cavity.

APICAL THORACOPLASTY

A complete thoracoplasty has been used until recently to collapse apical cavities. It was felt that if only the ribs overlying the cavity were removed the result obtained would be unsatisfactory, since the remaining ribs would prevent the desired collapse. We now know, however, that such is not the case, and from our own experience and the experience of others, we are convinced that a partial thoracoplasty in selected subjects is all that is necessary. This partial thoracoplasty sometimes calls for the removal of only four or five ribs. The good results originally obtained have justified the procedure in most instances. A few bilateral apical thoracoplasties have been reported.

COMPLETE THORACOPLASTY

Complete thoracoplasty is done in three or four stages. This multiple operation has reduced the mortality considerably.

Hedblom [13] recently reported on a collected series of 3,762 patients which had been followed for from one to twelve years after operation; 35.3 per cent were symptom and bacillus-free, and were able to work; 22.1 per cent were improved and able to do some work; 5.5 per cent were not improved or were made worse by the operation; 3.5 per cent were not traced; and 33.6 per cent were dead at the time of the report. A large proportion of the patients are rehabilitated to the extent that they are able to return to their former stations in life and to resume their former occupations or activities. Many women marry, and there is record of twenty-two who have borne children since their operation, usually against advice.

In the experience of the Medical and Surgical Chest Service, Barnes Hospital, 140 patients operated upon by Doctors E. A. Graham and Duff Allen, twelve have died within a month after the operation, a mortality of 8.5 per cent. In an analysis of seventy-five cases in which the operation was performed before 1933 it was found that 29.3 per cent of the patients were able to resume normal activities and had no tubercle bacilli in the sputum, and no evidence of remaining cavitation; 28 per cent were classified as moderately to definitely improved (able to resume some part or all of normal activities, but with tubercle bacilli occasionally present); and 17.3 per cent designated as slightly improved (cavities smaller or absent, but sputum still containing tubercle bacilli and patients still unable to work, although improved in general condition). More than 50 per cent of the patients seem clearly to have been benefited by the operation.

Accumulated evidence indicates clearly that if cases are properly selected, the operative mortality of complete thoracoplasty is relatively low and ultimate results gratifying.

The surgical technique of thoracoplasty is not discussed in this paper, because it is described in several books on chest surgery, particularly those by John Alexander,[14] Sauerbruch,[8] and Graham, Singer and Ballon.[2]

IN CONCLUSION

1. Collapse therapy has demonstrated its value in tuberculosis, and has been a great step forward in the battle against this disease, particularly in those who are otherwise doomed to die.

2. The simpler methods, particularly pneumothorax, is the one most extensively used, and should be tried before any of the other major measures are considered.

3. The results indicate that many years of illness and economic loss can be saved by judicious use of the various types of compression therapy.

4. Mortality statistics alone cannot be used as a criteria for the use of collapse therapy.

PEDIATRICS: SOME PRESENT DAY TRENDS*

By S. J. McClendon, M.D.
San Diego

It is not my purpose today to present a paper on original work, either of a research or clinical nature, but rather to summarize the progress which has been made during the year in the field of prevention of contagious disease, and in the field of endocrinology as it pertains to problems of growth and development. During the past few years a great deal of stress has been placed on various economic factors connected with the practice of pediatrics, so that we have been prone to lose sight of our fundamental duty to our patients, to give them the best that medical science can offer. For this reason it seems well to take stock of some of our accomplishments and shortcomings.

---

* Chairman's address, Pediatric Section of the California Medical Association, at the sixty-fifth annual session, Coronado, May 25-28, 1936.

PREVENTION OF CONTAGIOUS DISEASES

I feel that progress has been made in the past year in the attainment of one goal, that of the prevention of contagious diseases. All pediatricians are familiar with the proper procedures from the standpoint of recognized practice. However, we are constantly confronted with evidence which indicates that preventive measures available to us are not being utilized to their fullest extent. This is especially true of active immunization against communicable disease. In spite of repeated educational campaigns of school, health, and county medical society authorities, progress, although gratifying, has not been entirely satisfactory. The medical profession itself, and we pediatricians in particular, are largely at fault. Health departments should not be censured too much for the failure of preventive measures to function. Health departments have been undermanned and underpaid. Their efforts to stimulate the local medical profession into taking over some of their local public health problems have usually been unsuccessful. The result has been that agencies largely controlled by laymen have usurped the job, and are using successful means to increase the scope and degree of encroachment on private medical practice. Misinformation concerning many preventive measures has been disseminated by these agencies whose workers are untrained and ignorant, in so far as medical knowledge is concerned. Many of us have loaned our names to such agencies without being sure that proper medical information was being given.

I should like to summarize briefly, and as accurately as I can, the present status of some of the measures for the prevention of contagious diseases.

DIPHTHERIA

Diphtheria is now a preventable disease, but too often it is not prevented. The reasons are that immunization is not available to all who should have it, that it sometimes is improperly carried out, and that it is sometimes refused. All children should be actively immunized against diphtheria. Children who manifest allergic tendencies should not receive horse serum products, and should be tested for sensitivity to any goat products used. Otherwise there are no exceptions. The ideal age for immunization is six months. Reactions are slight at this age, and protection is assured during the most susceptible years. Children above seven years of age should be tested by the Shick method to determine whether immunization is necessary. If a positive reaction is obtained, a skin test of the material to be used for immunization should be made prior to its administration. The best material available for immunization at the present time seems to be the toxoid prepared by the method of Ramon. From two to three injections at intervals of three weeks should be given. Some still prefer to use the three doses of goat toxin-antitoxin, which is a satisfactory product. Alum toxoid, which is given in one injection, is very resistant to tissue absorption; for this reason it acts as an irritant and not infrequently leads to abscess formation. One of the remaining problems in this field is the perfection of a satisfactory one-dose immunizing agent, and this no doubt will be one of the accomplishments of the near future.

There has been considerable controversy regarding the value of the Shick test. The test can be said to be unnecessary in the case of a child under six years of age; in the cases of children above this age it should be used to determine whether or not active immunization should be given. The test should be used also to determine whether or not immunization has been successful. For this purpose it should be made three months after the injections have been given; if a positive reaction is obtained, an additional dose of toxoid can be administered. Occasionally a child may be immunologically inert or incapable of responding to any antigenic substance. Shick test toxin in peptone is the most practical material, because of its stability, for the average practitioner who tests children individually. If large groups are to be tested, undiluted toxin is probably better. Interpretation of the reaction should be made on the third day; if it is negative at that time, it should be observed again on the seventh day.

SCARLET FEVER

Active immunization against scarlet fever by means of injections of small, gradually-increasing doses of toxin derived from the scarlet fever streptococcus has been advocated. The toxin is administered over a five weeks' period at weekly intervals. This immunization may be of value for nurses, children in orphanages, etc., but it should not be recommended as a general routine preventive procedure. In the first place, the severity of the reaction is frequently greater than that of the disease itself, and in the second place the degree and duration of the immunity conferred is uncertain. The committee of this section and of the American Academy of Pediatrics for consideration of such immunization decided that the material available at the present time is unreliable. The zeal of biological detail men is great, however, and many physicians are attempting this immunization.

TYPHOID FEVER

It has been thought that typhoid fever does not constitute a real menace in the United States except in certain sections where the standard of living is generally lower. Experience in recent outbreaks has shown us that our present method of inoculation does not confer sufficient protection in the presence of especially virulent or overwhelming numbers of typhoid bacteria. It is suggested that typhoid inoculation, repeated every two years, be given to doctors, nurses, children going to summer camps and travelers to the Orient and Europe, but universal administration of typhoid vaccine is not recommended.

WHOOPING COUGH

One of the real problems of infancy and childhood, the solving of which has met with some encouragement of late, is the prevention of whooping cough. For years the seriousness of the disease has stimulated studies in its prevention, but any immunization heretofore attempted has been of no value. Recently much enthusiasm has been aroused by the work of Frawley, Krueger, Sauer, and Madsen, with freshly isolated strains of hemolytic pertussis bacilli. The use of fairly large doses, 8 cubic centimeters, of Sauer's vaccine has in my own hands seemed to be preventive in the majority of children. The proper dosage of vaccine, and the degree and duration of immunity obtained are problems to be solved. We cannot yet say that we have in this vaccine an active immunizing agent as dependable as is diphtheria toxoid, but the results of clinical trials are encouraging. Convalescent serum or adult whole blood has been used with good results as a temporary prophylaxis against pertussis.

SMALLPOX

Smallpox vaccination should not need discussion, but in a state like ours, in which there are constant endemic foci of the disease near by in Mexico, and in which active campaigns against vaccination are waged by large numbers of the population and even by many of our physicians, the disease is a menace. Routine vaccination of all infants between the ages of 6 and 12 months should be the rule, the only precaution being that sufficient time, from three to six months, be allowed to elapse between smallpox vaccination and diphtheria immunization.

ANTERIOR POLIOMYELITIS

Prevention of anterior poliomyelitis has received much attention during the past year, but still remains one of our major unsolved problems. Two vaccines have been advocated by Park and Kolmer, men of high standing in preventive medicine. From evidence available at the present time, however, we are not ready to say that these vaccines may be used routinely or even experimentally without some hazard.

MEASLES

The active immunization of measles remains another unsolved problem. The passive immunization, or modification, by whole blood, convalescent serum and immune globulin (placental) is an accomplished fact, and is being used very extensively with good results.

TETANUS

During the past year a tetanus toxoid has been developed which apparently causes a very rapid rise in antitoxin in persons previously immunized. If it is administered to such patients at the time of injury, a sufficient rise in the antitoxin level is obtained within the incubation period of the disease to protect them against tetanus. This material does not cause the serum reactions so frequently seen following the usual tetanus antitoxin injections. It has no value as a therapeutic agent, however, and should not be used at the time of an injury as a prophylactic agent in a patient who has not been actively immunized previously.

SOME TOXINS, ANTITOXINS AND TOXOIDS

A new meningococcus antitoxin has been advocated and introduced by Ferry. This probably does not differ, contrary to some reports, from other similar products, and should not be used on the assumption that it is a true meningococcus antitoxin. Evidence so far is not convincing on that point.

Staphylococcus toxin, antitoxin and toxoid have been subjects of a great deal of discussion. Toxoid is apparently a useful agent in the treatment of chronic staphylococcus skin infections, but it does not seem to be specific. There is no convincing evidence that this product is of any value in infections other than chronic pyodermias. Staphylococcus antitoxin seems to relieve certain symptoms in septicemia and occasionally appears to prevent early death. No definite bactericidal action has been proved in subacute or chronic pyemia and osteomyelitis.

BRONCHOPNEUMONIA

Although the management of bronchopneumonia should perhaps not be included among communicable diseases preventable by immunization, I should like to mention here one weapon at our command which I have found very helpful in the control of this disease. I refer to transfusions of whole blood. Specific curative agents of many kinds have been advocated by various observers, but except for Type I pneumococcus serum, which is not used as generally as it should be, their use constitutes a hope rather than a cure. Transfusions in cases of pneumonia, instead of being hazardous procedures, are almost invaribly beneficial; and there need be no fear of embarrassing the circulation even in those cases in which the situation is grave from the onset. Frequently transfusion is followed by a drop in temperature and marked general improvement. Such improvement may not seem to be maintained, but in the case of the very ill infant it may be sufficient to throw the balance to the side of recovery. In infants, intraperitoneal transfusion of 200 cubic centimeters of whole, properly cross-matched blood may be used. In older children the direct method may be employed, using a local anesthetic for cutting down on the veins if necessary. I have found that the adoption of transfusions as a part of the routine treatment for severe bronchopneumonia will frequently save lives and almost invariably shorten the duration of the illness. Even repeated intramuscular injections of from 40 to 50 cubic centimeters of whole blood, at two or three-day intervals, will be found to be surprisingly helpful.

ENDOCRINOLOGY

I have left the discussion of the field in which I have been particularly interested to the last, that of endocrinology as it pertains to growth and development. This field should be a vital one for the pediatrician, because he is concerned fundamentally with the growth and development of children.

THYROID THERAPY

The value and specificity of thyroid therapy I do not need to mention, although there is still need of educational work in this field.

PITUITARY GLAND

The gland about which the most discussion has centered during the past year is the pituitary gland. The known hormones derived from this gland which are of particular interest from the pediatrician's standpoint are the thyrotropic, the gonadotropic and the growth hormones. The thyrotropic hormone apparently acts as a stimulant to the thyroid, and it is around the functions of this hormone that much controversy has arisen. Riddle claims that this hormone is responsible for growth, and that there is no such thing as an actual growth hormone.

GONADOTROPIC HORMONE

The gonadotropic hormone is responsible for the development of sex organs, and in its turn stimulates the development of other sex hormones, among which is antuitrin S, which has been used with success, in some hands, in certain cases of undescended testicle.

From animal experimentation we are fairly convinced that the acidophilic cells of the anterior lobe of the pituitary secrete a hormone which stimulates growth in every body structure, and especially skeletal growth. This hormone, as isolated by Evans, has produced most satisfactory results in animal experimentation. Varying results have been reported in clinical trials. Many workers are very enthusiastic about them. Personally, in a series of fifteen cases of pituitary dwarfism, I concluded that growth was stimulated only slightly by injections of the hormones. Standardization of material and determination of dosage may result in more striking changes. In four cases of mongolism, I obtained no results whatever; this, I believe, has been the experience of most workers with this form of treatment of Mongolian idiocy.

To my mind the field of endocrinology is one of the broadest in pediatrics. I believe that future developments in it will have far-reaching effects, and that through its teachings many of the now seemingly hopeless abnormalities of childhood may be corrected and normal adulthood assured.

IN CONCLUSION

I have limited myself in this discussion to the progress made in the fields of prevention of communicable disease and one phase of endocrinology. The conclusions to be drawn from the work in these fields may be applied to all the problems of pediatrics. Were it not for the opportunities offered us to conquer these problems, we might become discouraged; but we cannot look back over the progress of the last fifty years without experiencing a thrill of enthusiasm for the possibilities for even greater progress in the years immediately ahead.

SLEEP DISORDERS IN CLINICAL PRACTICE[*]

By Franklin G. Ebaugh, M.D.[†]
Denver, Colorado

PART II[‡]

There are many adjuncts to psychotherapy, some of them essential aids, others apparently acting principally by suggestion. Employment of these adjuncts, however, is no substitute for the rational treatment of the causes.

ADJUNCTS TO PSYCHOTHERAPY

Hydrotherapy.—Hydrotherapy in all its variegated forms is one of the soundest and most practical adjuncts to the treatment of insomnia. It allays tension and promotes relaxation, permitting sleep to take place. While its greatest usefulness is in severe psychiatric disorders, it may be very helpful in ambulatory cases. A warm tub (36 degrees Centigrade) at night for thirty to sixty minutes, is possible to most patients. In the hospital, sponging, the warm wet pack, the cold wet pack, the continuous tub, the needle shower, the Scotch douche, are very important means of sedation for disturbed patients. Both cold and warm wet packs are sedative in action, but the cold packs are more powerful due to a strong initial vasoconstriction. Patients with damage to the vascular system in cold wet packs must be watched so that they do not go into shock. Senile patients in warm wet packs may develop a hyperpyrexia. A cold compress or ice bag to the head may be a great comfort. Apprehensive or suspicious patients must have the procedure explained to them or else be put in tubs. Only robust natures should be subjected to the rigors of cold douches, sprays, etc.

Electricity. — We do not use electricity, but E. Meyer [3] reports "that a weak anodal galvanic current to the head can help sleep along with other methods is undeniable. Use of the now highly publicized high-frequency wave apparatus with glass electrodes is to be avoided. Leduc waves seem to help, as do even minimal doses of x-ray on the 'tweenbrain' (diencephalon) in monthly series of three to four sittings (Wieser)."

Other Methods.—Tradition has sanctioned many tricks by which sleep may be wooed: drinking hot fluids, taking walks, counting sheep jumping over a fence, with the well-known objection that by the time one has counted 30,000 it is time to get up, and other variations of this idea. The reading of light (or heavy) literature, carefully graded to the patient's taste, has become fashionable. Methods for promoting relaxation are many, the best known being that of Dr. E. Jacobson, who has written a best seller, "You Must Relax." He believes that muscular relaxation can be voluntarily induced, but we are inclined to believe that such relaxation is as difficult to induce as sleep itself.[22] It is essential to note that we do not will ourselves to sleep, we allow ourselves to go to sleep. All active efforts to induce sleep, therefore, seem useless.

---

[*] From the Colorado Psychopathic Hospital and Psychiatry Department, University of Colorado.

[†] Guest-speaker address, read before the California Medical Association, Coronado Beach, May 27, 1936.

[‡] Part I of this paper appeared in the July issue, commencing on page 5.

SEDATIVE AND HYPNOTIC DRUGS

Sedative and hypnotic drugs are usually the first remedy sought by patient and doctor, after tricks like those mentioned have failed. Most of these drugs fall into one of the following groups:

1. Opium and its derivatives.
2. Hyocin and related drugs.
3. Bromid salts.
4. Sulphone group.
5. Chloral group.
6. Paraldehyd.
7. Barbituric acid derivatives.

Opium and its derivatives should not be used except for relief of intense pain or other standard medical indications. The danger of addiction is too great to permit free use in chronic cases, although some doctors use tincture opii with apparent impunity. Pyramidon is one of the best of the coal-tar analgesics, and should be tried before codein or other narcotics; although the researches of Kracke, Jackson, Madison and Squier, in respect to the pyrazolon derivatives (antipyrin, amidopyrin or pyramidon and melubrin) in causing granulopenia in specific instances must be noted.

Hyoscin has been used in cases of extreme excitement and panic states, but we do not believe that its use is necessary in the great majority of cases, and actually we never use it.

Bromid salts, introduced in 1853, have a cerebral depressant action which is sedative and only incidentally helps sleep. Bromids are eliminated slowly through the kidneys; the dangers of toxic accumulation are greatly increased in the arteriosclerotic and the aged, or in any toxic-organic disorder where metabolism is disturbed. A large fluid intake, supplemented by table salt, must be employed to insure adequate elimination. We much prefer using small doses of other drugs given throughout the day for the same purpose in order to avoid the possibility of skin rashes and toxic symptoms. While well controlled use of bromids is legitimate, the many cases of deliria and other complications resulting from their misuse due to self-medication, places an obligation on a physician to warn his patients against them.

Sulphonmethane (sulphonal) was introduced in 1888, but general usage was discontinued because of slow uncertain absorption, with the likelihood of toxic effects from prolonged use. The general effects are the same as that of paraldehyd and chloral hydrate (Webster: Toxicology, 1930). Headache, malaise and dizziness are often present even with medicinal dosages. Trional and tetranol have practically the same effect. They may be useful in early morning waking because of the prolonged effect.

Chloral hydrate, 1869, has actions similar to those of alcohol and chloroform although they are less strong and more lasting (Webster: Toxicology, 1930). The action is swift, and there is usually no after-effect with small doses. Large doses cause a burning sensation in the mouth, throat and stomach, with nausea and vomiting due to the local irritation. The chief action of this drug is its depressant effect upon the central nervous system. This drug has become unpopular in many circles, since death may occur suddenly when the heart has been weakened, as in delirium tremens and in the insomnia of continued fevers. We do not use it for these reasons.

Paraldehyd is one of the most useful drugs we have where a powerful effect is desired, since there is a wide factor of safety between the effective dose and the minimal lethal dose; there are few toxic effects which accentuate already existing damage to the kidneys and heart; it does not depress the heart and respiration; it is rapidly eliminated; the sleep is normal, and with ordinary doses without after-effects. The disadvantages are its disagreeable taste and odor, the latter persisting for some time. The ordinary dose of three cubic centimeters raised in severe cases to 15 cubic centimeters, or, better, a teaspoonful can be given every hour until effective. It is best given with iced orangeade to help disguise the taste. Since sleep ensues within fifteen minutes, the patient should be in bed when the drug is given.

Paraldehyd should be given in any case where moderate doses of the barbiturates (barbital, gr. v-x, phenobarbital gr. iss-iii, sodium amytal gr. iii-v) are ineffective. If more powerful sedation is necessary, provided there are no contraindications, sodium amytal should be given *slowly* intravenously. Paraldehyd will be found useful in all the *deliria,* especially *delirium tremens* and in *pneumonia* after the fifth to sixth day; in *manic* patients who are losing too much sleep from overactivity, losing weight, etc.; in *agitated depressions*; in *tension and anxiety states*; in *severe psychoneuroses* where the vital functions are disturbed; in *excited schizophrenics*; in *arteriosclerotics* where reversal of sleep rhythm is found; in *panic* states. It should be used whenever possible in preference to other strong sedatives and hypnotics.

A note of warning should be sounded about the possibility of chronic addiction to paraldehyd. This may occur in chronic alcoholism when the patient has learned to tolerate the drug as he has alcohol. "The symptoms resemble in some respects those of chronic alcoholism and a condition not very unlike that of delirium tremens may result." (Legal Medicine and Toxicology, Peterson, Haines and Webster, Saunders, 1923.)

The *barbituric acid (malonylurea) derivatives* are the most widely used sedatives and hypnotics for symptomatic treatment at the present time. They increase the efficacy of aspirin, phenacetin, and pyramidon. They are somewhat slower acting than chloral hydrate, but more rapid than sulphonal derivatives. They are easy to take, the toxic effects minimal with medicinal doses. They are cumulative and, consequently, effects must be carefully gauged in arteriosclerotics and the aged, in cases of damaged kidneys and impaired circulation. Since they are respiratory depressants, care must be exercised not to use them in upper respiratory infections and in influenza.

The common preparations are: barbital (diethyl barbituric acid), introduced as veronal in 1903;[16] sodium barbital (medinal), which is soluble and may be used hypodermically; phenobarbital (luminal, phenylethyl-barbituric acid, 1912) is slower acting, more slowly eliminated, and has a more profound effect. These are the official preparations. New and nonofficial remedies include sodium phenobarbital, neonal, ipral. Propanol, dial, allonal, and amytal are more recent drugs. The latter, amytal (iso-amylethyl barbituric acid) has a sodium salt which found an immediate popularity. It is quick-acting, quickly eliminated, with few toxic effects and little hang-over from ordinary doses.

Toxic symptoms may resemble alcoholic intoxication, with foul breath, nausea, characteristic slurring speech, disorientation, confusion, memory loss, tremors, ataxia, and even hallucinations and delusions. Skin rashes are common in chronic poisoning. I would like to mention the fact that, although picrotoxin is generally thought of as a medullary stimulant, its use in a case of barbiturate poisoning with delirium in March, 1936, produced marked cortical stimulation. Although this has not been fully verified, I mention it as a possible adjunct to the regular treatment of barbiturate poisoning. Maloney found it useful for this purpose in animals. (Maloney, A. H.: Barbital: Picrotoxin, Proc. Soc. Pharm., 1931.)

Many patients are afraid that these drugs are "dope," expressing a deeply rooted prejudice, probably grounded upon stories about slavery to drug addiction. It is necessary to explain in detail that they are not narcotics, and will not cause true addiction with withdrawal symptoms and other physiologic changes. We distinguish between the latter and the "psychic dependence" upon a drug, which is based upon some personality disorder helping those afflicted to escape the harsh realities of life.[46] Chronic alcoholism comes to mind as an analogous condition. This does not mean we minimize "psychic dependence" or chronic alcoholism, since both are often very profound disturbances. Just as we are on the alert to prevent true addiction to narcotics, we should be on guard against a slavish dependence on any other drug.

CAUTION IN USING DRUGS

The physician prescribing drugs must take the responsibility for any complications which may arise due to their ingestion. He should know the toxic symptoms accompanying prolonged usage or overdosage. It is becoming a commonplace in the literature that a doctor may well limit himself to a few common useful drugs and become thoroughly acquainted with them rather than to change to every new product offered by the drug houses.[1, 20, 34, 38, 40, 47, 48, 49] "Careful clinical observations of all the possibilities of a few drugs is a suitable problem for study in private practice."[20] The amounts prescribed should be carefully controlled, so that deliria or suicidal attempts may not result. To prevent the latter we believe that these drugs should be sold only on a physician's prescription.

Drugs are best administered in capsules, so that the identity and amounts are concealed and can be changed without comment from the patient. The dosage should be reduced frequently in a consistent attempt to make the patient independent of his "crutch." No patient taking drugs should be discharged. Some authors (Muncie) do not believe that drugs are indicated in the pure psychoneurotic reactions. They are most useful in the affective disorders, and in the toxic-organic groups where there is specific indication, like the reversed sleep rhythm in arteriosclerotics, or some obvious factor causing an acute condition.

REPORT OF CASES

The following cases are cited in order to summarize our approach and to illustrate the actual management in practice.

CASE 1.—O. M. is a 56-year-old white, married farmer, who complains of insomnia, especially of the early morning waking type. Explicit questioning elicits lowering of mood, decreased work efficiency, slowed thinking, with typical biologic changes of constipation, decreased sense of taste and appetite, easy fatigue, and impotence. The mood disorder began about nine months before examination, but became acute three months ago with great concern about financial difficulties, quarrels with a son-in-law, fear of the future, fear of insanity and loss of health due to insomnia. Adequate explanation of his symptoms as manifestations of a mood disorder, together with mild sedation and warm sedative baths at home (sixty minutes at 36 degrees Centigrade) brought about a rapid change. Barbital, grains 1½, at 8 a. m. and 4 p. m., was only necessary for five days. The patient saw the relation between his illness and the situation he was in rather easily and made positive constructive plans to improve the situation. He was seen five times in four weeks without any loss of working time.

✓ ✓ ✓

CASE 2.—Fern R. is a 28-year-old, single, white female, who, after an indifferent school career due to recessive behavior as well as a mediocre intelligence, lived with relatives following graduation from high school at the age of eighteen. She discovered accidentally, while visiting a married sister in an adjacent city, that she was much happier away from her rather demanding mother. Her insomnia began insidiously about eight months before examination following her return to her mother, becoming acute five months after the onset, when she had to help the now invalided mother to care for another sister and her two children who had come to live with them. She had previously received medical treatment for a nonspecific vaginal discharge and headaches.

Therapy consisted of explaining the patient's resources in an attempt to utilize her assets as well as her liabilities. Through repeated interviews, employing the methods mentioned, she was gradually able to face the real problem, that of emancipation from her mother, without feelings of self-condemnation. She increased her socialization, found more spontaneous interests which brought satisfaction, and was able to live at home for months at a time without a recurrence of the complaints.

Due to the apprehensiveness and tension present, she was given barbital, grains 1½, at 8 a. m., 12 noon, and 8 p. m., but this was cut down gradually after the early subsidence of the insomnia in about two weeks. At first the noon, then the morning dose was omitted. The patient was urged to take a shower at noon followed by an hour's rest; a warm bath for an hour was recommended at night when the patient felt restless.

✓ ✓ ✓

CASE 3.—T. R. is a 32-year-old married housewife, who complains of insomnia, feeling "on edge," being easily upset by food, unable to enjoy company, with occasional attacks of constricting sensations in her throat, accompanied by cardiac sensations. Her restlessness and emotional lability had caused an internist to suspect hyperthyroidism, but the variable metabolic rate, the coarse tremor, the real restriction of energy, the cold, clammy hands, decreased appetite, decreased pulse rate during sleep, were differential points suggesting an anxiety state. Acquaintance with the case brought out the fact that these symptoms developed in the third year of her marriage to a successful minor executive for a utility company. She had no children, hobbies or interests beyond caring for her house and husband. They had been together a great deal during the first two years of her marriage, but after his promotion to a position which required traveling, she began to have the complaints mentioned, with concomitant loss of weight, increased feeling of fatigue, gastric disturbances, poor elimination, spells of easy irritability, coupled with a tendency to depression, inability to concentrate as well as formerly, etc. Physical and laboratory examinations revealed no organic disorder. She hesitatingly revealed, after several interviews, that since her husband's frequent absences she had been lonely and felt frustrated. She intimated that, not without reason, she suspected her husband of infidelity (flirtations) when away from home. This formed a large part of her ruminations while awake at night. Association-motor studies showed tension on key words like "husband," "journey," "old age." She was gently urged to describe her difficulties at some length in three interviews before any elucidation of the cause of her complaints was entered upon. Then the patient was led by questions to review her symptoms in relation to her fear of being deserted, her loneliness and her frustration. Means were discussed whereby she could occupy her time and energy to better advantage. The husband was informed of the nature of his wife's complaints, whereupon he signified his willingness to help treatment procedure. With his coöperation the patient was given reassurance that her security was not in danger. Quick relief from symptoms resulted when obvious changes suggested to them were made. It is important to note that the patient did not want to talk about her suspicions even when directly questioned about the content of her ruminations. Persistence must be shown, for the path to true psychotherapy is not always an easy one, but it amply rewards the pains taken in sound therapeutic results.

IN CONCLUSION

If sleep is thought of as a function of the whole person, the treatment is directed against the sleep disorder at the level on which it occurs. Painstaking effort is made to rule out all environmental and toxic-organic causes. If the cause is rooted in some malfunction of the personality, the complaint is studied in great detail in relation to the personality who has it. The serial picture obtained by intimate acquaintance with the patient's problems, assets, liabilities and goals suggests specific treatment measures for that individual. The general types of these measures are known as aeration or ventilation, suggestion, reassurance, desensitization, and reëducation. These methods are as vital and as effective as the physician employing them. A few useful sedative and hypnotic drugs should be discreetly employed only as a "crutch" along with other adjuncts (hydrotherapy, packs, and exercise) to help establish rapport and to break the vicious cycle of fears often initiated by insomnia. These methods are effective in a large majority of cases.

PSYCHIATRY: REASONABLE ESSENTIALS FOR ITS PRACTICE*

By Sydney Kinnear Smith, M.D.
Oakland

In the privacy of our own professional chamber—as we may consider our neuropsychiatric section meeting—it has occurred to your chairman that it might be of some practical value to look at ourselves in terms of the patient's reaction to us, and to our own personalities.

PHYSICIAN'S PERSONALITY

If there is any branch of medical science where the personality of the practitioner is of importance, it is in the realm of psychiatry. It is entirely conceivable that an emotionally unstable individual might irrigate bladders successfully, or that an extremely colorless personality might remove a nasal polyp to the satisfaction of all concerned, but it is difficult to imagine an emotionally unstable psychiatrist being of much real value to his patient.

In the first place, the patient comes to the psychiatrist oftentimes with a preconceived idea that the psychiatrist can read his patient's thoughts and by some mysterious power can see "right through him." We are all perfectly familiar, through our social contacts, with the oft-expressed idea that our friends have, that they are being "psyched" when they talk to a psychiatrist. There may be those among us who combine the attributes of a Sherlock Holmes and of Sigmund Freud, but such gifted individuals are, unfortunately, rare in our profession. Consequently, our first effort in meeting a patient should be to correct any such erroneous impression, for we know well enough, if we are honest with ourselves, that we cannot live up to it, and that if we persist in trying to delude ourselves or our patients in this way, a crash is inevitable. We are not suggesting that we forthwith inform the patient that we are merely ordinary citizens without especial abilities. This is not true, for certainly the major portion of those practicing psychiatry in this country are well equipped and trained individuals. Our point is that, without losing prestige with the patient, we should make them feel that we are properly equipped to lead them out of their difficulties, but are not the possessors of any mysterious or occult power; that we are in no way akin to the clairvoyant. We believe that the more matter-of-fact path in this regard is the one that will lead more surely to the satisfactory physician-patient relationship.

FIRST CONTACT IMPORTANT

We cannot stress too much the importance of the first contact, and the building up on the part of the patient a set of reactions toward the psychiatrist that are of positive value in our subsequent therapy. Some of you may call this the establishment of a positive transference, but the thing we have in mind is something more comprehensive than transference in the analytical sense. It is a combination of a feeling of respect combined with a sense of security.

This establishment of a rapport depends, of course, on a number of things. In the first place, as we have mentioned, is the need of avoiding the atmosphere of mystery. It may work temporarily, but it is short-lived, and its death is violent.

In the second place, and somewhat akin to this first suggestion, is the avoidance of an attitude of a too profound wisdom. We find this matter referred to not infrequently in psycho-analytical literature, and it may well be emphasized in even a wider application than psycho-analysis. Jeliffe has referred to the wise nodding of the head as the physician intimates that he has anticipated the patient's story as something to be avoided.

The next thing that the patient may reasonably expect of us is the avoidance on our part of rash promises, given as a result of undue enthusiasm, or because we are fearful of telling the patient the truth. We believe that we are just when we say that as psychiatrists we are under an even more careful scrutiny from our patients than the average physician and, consequently if, in an unguarded moment we make promises that we can not live up to, we soon pay the price in the loss of respect from our patients. We believe that the most desirable procedure is to explain, as reasonably as is possible to our psychoneurotic, and even to our psychotic patients, the method of our anticipated procedure, giving them as nearly as we can an intelligent idea of why such a procedure is to be followed. There is no doubt but that we get a greater degree of coöperation from patients so instructed.

---

* Chairman's address, Neuropsychiatry Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

MAINTENANCE OF BALANCE IN JUDGMENTS

Next we come to the consideration of balance in our procedure. By balance we are referring to the ability on the part of the psychiatrist to use to the best of his ability, the features of each form of psychiatric procedure most suited to the case in question. Suggestion, persuasion, hypnosis, analysis, and chemotherapy, each have their place in our armamentarium. We believe that the majority of our profession in this country adhere to such an attitude, and to this larger group we are not speaking, but we are keeping in mind that minority who are, temporarily at least, carried away by the therapeutic possibilities of one of these lines of procedure. We are thinking of that class of enthusiasts, who, as Gordon Holmes once said, are worshiping a God called Freud, or of our ardent hypnotists, and of many other one-sided, oft-times misguided physicians. We are thinking of the type of procedure that we had the misfortune to witness not long since of a well trained, highly enthusiastic analyst who proceeded hopefully to work out the complexes of a bed wetter who had chronic cystitis—a fact that was not determined by examination until three months after the analysis was under way.

Our aim in this communication is not to ridicule the analytical or any other procedure, but rather to stress the need of a wider vision that allows the use of each of these procedures as indicated. We would not expect a surgeon to insist on the electrocautery for all ailments in his field, granted that for certain malignancies electrocautery may be the weapon of choice. A surgeon who would so insist would be considered poorly balanced—as the psychiatrist should be who sees therapy in terms of single procedures. We believe that these single-track practitioners are bringing ill-repute to psychiatry and psychiatrists, and are wandering far away from the enlightened precepts of the leaders of our profession—Myers, Campbell, Hoch, Amsden, Hart, and a host of others.

BACKGROUND OF THE PSYCHIATRIST

It may be apropos to think briefly at this point of the type of person who should consider psychiatry as his field; for many of the pitfalls that we are considering are the result of the wrong type of individual having entered the ranks of psychiatry. Briefly stated, we feel that the individual entering psychiatry should essentially be the sort of person that we may somewhat inaccurately speak of as being subjective-minded in contrast to the objective-minded person. In other words our ranks are better filled by the philosophers in medicine than by the skilled mechanics. Patience and vision are requisite, and are qualities that our objective-minded individual cannot be expected to produce in adequate amount. These persons will find themselves much more at home in such realms as nose and throat and surgery, rather than in psychiatry.

Our ideal practitioner in the realm of mental science needs, especially, a wide cultural background. The diagnostic criteria of Kraeplin are excellent, and the nomenclature of the American Psychiatric Association, admirable; but neither provide the cultural equipment that is essential to the wide vision necessary in dealing with psychiatric material.

As has often been pointed out, it is insufficient to consider patients as individual units, but rather they must be thought of as fitting into a world picture. How can we do this satisfactorily if we haven't a world picture ourselves? To have this we must have a knowledge of racial development, world history, some background of literature, art and thought throughout the ages. Even current Broadway successes and best-sellers should be more than names to us.

Aside from being able to fit the patient into the wider setting of a world picture, we should be able to meet him reasonably well at his own intellectual level. If he chances to discuss the paintings of Van Gough he has a right to expect that the psychiatrist will not look blankly at him as though he were discussing a breakfast food. Wagner should mean more than "heavy music," and Eugene O'Neil more than the producer of plays of questionable morals, and "Idiot's Delight" more than another term for autoerotism. We will gladly grant that any full knowledge of the variety of the intellectual demands upon us is well nigh impossible, but we do contend that to practice psychiatry properly we are forced to keep up a voluminous reading, much of it not found in our scientific journals.

EMOTIONAL BALANCE OF THE PSYCHIATRIST

And finally, we come to the matter of emotional balance on the part of the psychiatrist. All too often we have all been told that the psychiatrist is practicing in that field of medicine because there is something wrong with him emotionally, and next we have been told that the psychiatrist ultimately goes crazy. These popular fancies are too ridiculous to discuss, but we must admit the need of an emotional balance on the part of the physician dealing with emotional disorders. The thought, often expressed, that one can understand their patients better if they have gone through similar experiences may have some truth in it, if the psychiatrist has gone through the experience to a successful adjustment. Unfortunately we cannot supply every schizophrenic with a recovered schizophrenic physician. At the outset of his career the person anticipating psychiatry should evaluate his own emotional equipment, and if he finds it faulty, should attempt its rectification before undertaking the practice of psychiatry. Individuals who are unduly aggressive should hesitate to enter the ranks until this characteristic is well in hand.

The inferiority complex has no place in the practice of psychiatry, unless satisfactorily compensated for. The same should be said for the other evidences of emotional instability.

IN CONCLUSION

In conclusion, may we summarize our reflections on the requirements of psychiatric practice by defining an adequate psychiatrist. Such an ideal individual might be described as being equipped with a carefully planned training in the theory and practice of psychiatry; a person able to avoid the pitfalls of therapeutic fads and fancies; one big enough in his caliber and outlook to avoid an attitude of mystery, and unpossessed wisdom; one who, from reason of his intellectual and cultural background, is able to consider his patient as a part of a community and world scheme rather than as an isolated unit. Added to these requirements as an essential factor is the presence of an emotional stable personality.

230 Grand Avenue.

EPITHELIOMATA OF THE SKIN[*]

SOME CLINICAL NOTES

By Douglass W. Montgomery, M.D.
San Francisco

Discussion *by Hiram E. Miller, M. D., San Francisco; H. J. Templeton, M. D., Oakland; Arne E. Ingels, M. D., San Francisco.*

The Diagnosis of Epithelioma.—Usually the diagnosis of epitheliomas of the skin is easy, so easy in fact as in itself to be a source of error. There is the elderly patient with keratoses of the skin, as well as the graver malignant lesion or lesions. The epithelioma is usually an ulcer of small size, indolent, and having a rolled or nubby border caused by epithelial infiltration, which itself differs by its waxy appearance and firmer consistency from the inflammatory infiltrations. Under such circumstances the diagnosis is eminently simple. Besides the above there is also the situation of the growth on the face or on the back of the hands. However, one must not forget that epithelioma may occur wherever epithelium is. I shall not quickly forget a lesion situated on the anterior surface of the thigh just above the knee that looked exactly like an ecthyma with its prominent hard, dark, tightly adherent crust situated in a bright field. The affection, however, had been present altogether too long to be due to such a swiftly moving affair as streptococcic infection. It had been present for nineteen years but had been growing more rapidly of late. After soaking off the crust with boric acid solution the characteristic rolled border was revealed.

IMPORTANCE OF THE ADVANCING INFILTRATIVE BORDER

The most important feature, both symptomatically and pathologically, is this advancing infiltrative border, and this can assume many different forms, such as a thin line, or a rolled or nubby border. But the most striking variations occur when the infiltrating cells degenerate either unusually slowly or unusually quickly. In the latter the degeneration occurs so quickly that no visible infiltration takes place, and consequently there is no characteristic border. On curetting, a rather deep hole is exposed, with sharp, steel edges, and the contents have a glairy appearance likened to rabbit flesh. In the other case the epithelial cells show little tendency to degenerate and the infiltration extends out under the surface as a plate. Under such circumstances, the attention being fixed on the ulceration, the smooth plate the color of old ivory, extending out beyond the ulcer, may escape notice. In fact, not long since I nearly made this mistake myself. At times this kind of infiltration gives rise to a remarkable lesion, looking like a flattened button with rounded borders and sunken center. It has the yellow, old ivory color above mentioned and the epithet "morphea-like," given by Hartzell, is one of the finest similes in medicine, and indicates how easily one may slip in the diagnosis.

It is self-evident that the whole infiltration must be treated in order to secure a perfect result. The elusiveness of this mistake goes beyond the immediate future, as the wound made in treating the ulcer may heal perfectly, leaving one with a perfect sense of security. Furthermore, the treatment by radiant energy alone may also be followed by only temporary healing, as these infiltrating cells are quite resistant and they are covered by an intact surface epithelium which constitutes an excellent screen for the subjacent tissues, hindering the full action of the rays.

THE TENDENCY OF SEBORRHEIC SKIN TO CANCEROUS DEGENERATION

One must never forget the type of skin on which an epithelioma occurs. It is almost invariably seborrheic, that is to say, it is either unduly dry and brittle with a tendency to develop dry hard crusts, under which the epithelium may degenerate into epithelioma; or the skin may be oily, with the formation of greasy crusts with a tendency to malignant change. These seborrheic types of skin usually occur in the aged, or at least in those well up in years. They may, however, happen in the years of full manhood, with the patient showing all the signs of vigorous health, possibly too vigorous health, as overnutrition leads exactly to the same degenerative end as undernutrition.

REPORT OF CASE

Case 1.—Such was the case of a markedly full-blooded man, forty-six years of age, who sought freedom from an epithelioma of the right temple, where he had received an injury five years previously. The lesion at its upper edge had evidently healed, leaving an indurated uneven red surface. Still farther above this there was a desquamating patch, and on the left temple there was a small nodular epithelioma. The seborrheic changes above adverted to had begun in the temporal regions, and the desquamating patch on the right temple showed that the tendency to malignancy extended beyond the region of full malignant change.

All of these lesions had to receive attention and, furthermore, one had to realize that other epitheliomata, independent of these, would inevitably arise on his overnourished skin. And any effort by admonition to cut down this nutrition in such a man would be preaching in the desert.

---

[*] Read before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

At times this seborrheic change in the skin is most profound, involving in the utmost disorder both the surface epithelium and the sebaceous glands.

A case report follows:

Case 2.—I once had under my care a powerfully built, middle-aged man with a florid rosaceous complexion. The nasolabial grooves, the "lineae dolorosae" of Alphonse Daudet, were deep and the corners of the mouth were drawn down, giving him the facies of the chronic dyspeptic. He had gingivitis with marked retraction of the upper gums in front, where there were a number of leucoplasic patches. His vascular system was as deeply affected as his digestive, and he had a pulse visible at the wrist. He had been a dairy farmer, and had always consumed large quantities of milk, cream and butter; and, even after abandoning farming and becoming a teamster, he said he was "right smart" on milk. Periodically, too, he was a heavy drinker. There were many crusts on the face and on the back of the hands; those of the nose were green in color. The whole red of the lower lip was occupied by a crust, and there was a crust on the median line of the red of the upper lip. The skin of the neck was a golden yellow, and deeply wrinkled in every direction.[1] This change I have observed only in outdoor workers, and it is most striking. He had a seborrheic eczema over the sternum that was curiously linear, looking like streaks of withered skin running downwards and outwards. The skin, as above described, was profoundly seborrheic, and on this skin in the lateral malar region there developed a soft, rapidly growing epithelioma, looking like a strawberry.

Instead, however, of being generalized, the seborrheic process may be localized.

Case 3.—Such was the case of a woman with dry atrophic epitheliomata in both earshells. In this location she had also an equivalent kind of seborrhea as being dry and hard, and the sebaceous orifices in this region were filled with dry, brown, horny plugs.

And, by the way, the hollows of the earshells are particularly apt to be seborrheic. Colcott Fox first drew my attention to the frequency of seborrhea in this situation.

CHANGING VIEW CONCERNING THE DEGENERATION OF THE EPITHELIAL CELL

Up to quite recently the epithet, cancer, has not been given to a lesion until it has infiltrated the subjacent connective tissue. With the increasing interest in the epithelial cell and its degenerations, this view is changing, and recently Louis Savatard has described what he calls psoriasiform carcinoma of the skin. He designates it as an intra-epithelial epithelioma. In it the cells show the degenerative lesions of epithelioma, but the epithelium has not dipped down into the subjacent connective tissue of the skin. Many so-called precancerous lesions on the skin would come within this category, as would Bowen's disease and also Paget's disease, whether of the nipple or elsewhere.[2]

EPITHELIOMA OF THE EARSHELL

Epithelioma of the earshell is frequent, and is usually easily diagnosed. There is a lesion, however, that occurs on the border of the ear which may be confused with epithelioma—"painful nodule." As its name indicates, it is very tender and causes trouble at night by contact with the pillow. The treatment for this affection is to split the skin over the painful spot and cut out a piece of the underlying cartilage. I had a patient who suffered both from epithelioma and painful nodule, each requiring its own form of treatment.

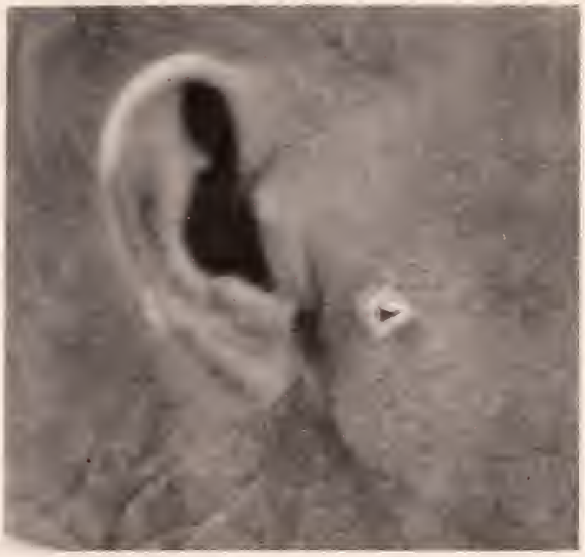

Fig. 1.—A keratosis of the cheek had been present for about five years. The whole area was seborrhoeic and the sebaceous glands showed through the thin light-colored skin as yellow fat granules. Nine months after the first visit a tuberous, easily bleeding epithelioma, as seen in the photograph, had developed which, under the curet, came out as a ball, leaving a shallow depression. On the neck is to be seen the deep wrinkles of the condition called cutis rhomboidalis nuchae.

It has always seemed to me that epitheliomata of the earshell tend to be decidedly more malignant than those of any other part of the skin, and I have attributed this to the fact that the earshell is one of the organs of our body that is slowly regressing. After treating an epithelioma of the earshell, I always warn the patient to return to the office on the occurrence of any persistent rough patch, so that it may be treated in its incipiency. I also regard epitheliomas of this region as particularly liable to metastasis.

EPITHELIOMATA ARISING FROM EPITHELIAL LININGS OF SEBACEOUS GLANDS

Epitheliomata, of course, may spring from the epithelial lining of a sebaceous gland, and are especially dangerous for three reasons: They lie deeper and, therefore, remain hidden for a longer time; they have not the benefit of the warning voice of pain; and they are more apt to be spinocellular, and, therefore, more malignant than those arising from the surface. The brother of a physician illustrated this variety.

Case 4.—He had a large sebaceous pore on the right cheek filled with sebum, and about it there was an extensive but well-circumscribed induration. There was a small lymph-node under the right side of the lower jaw, suspected to be metastatically infiltrated. The lesion had been present for four or five years.

Analogous to this, as growing unsuspectedly in the depth, was the case of an elderly man with an epithelioma of the navel which had been treated as a papilloma.

Case 5.—When I saw this patient, the navel was occupied by a red, hard, finely granular mass, which bled spontaneously. Below this, in the depth of the skin, there was an indolent indurated tumefaction at least three inches in diameter. The lymphatics in the left groin were enlarged, but freely movable; those in the right felt like small granules.

It is with such cases as these that the physician who first sees them is particularly unfortunate, as he is blamed for being either careless or for lacking in diagnostic ability, whereas the man who is finally consulted, when any tyro can make a diagnosis, is regarded as being shrewd and clever. There is an old saying: "Happy is the physician who is called last in a case."

Face Epitheliomata.—Epitheliomas of the skin are far more frequent on the face, particularly on the anterior aspect of the face, than in any other region. Next to the face they occur on the back of the hands. Both of these surfaces are exposed to light and to the inclemencies of the weather. I take it that light is more damaging in this respect than any other factor, and that it is particularly noxious for those who are naturally unable to form pigment and under the sun's rays do not tan, but burn.

Keratoses of the Hands.—For some unknown reason the keratoses on the back of the hands are different from those on the face. The skin in this region shows the effects of age more quickly than in any other region. It becomes thinner, loses its elasticity and looks faded. The keratoses are very much harder and more compact, and much more difficult to curet than those of the face. If care is not exercised in curetting, one is liable to rip the skin, often laying back a considerable flap, not at all desirable. With local anesthesia and a gentler, more persistent approach, and with the aid of liquor potassae to soften the hard masses, one can curet out these masses without ripping the skin.

Very often it is better to use a corneal spud rather than a curet. And by the way, the corneal spud is an admirable instrument, introduced into our office by my associate, Doctor Viecelli. It insinuates itself much better than a curet under the layers of epithelium, lifting them off layer by layer.

Strangely enough, these hard masses do not show anything like the same strong tendency to degenerate into cancer that those on the face do. We, however, from time to time do meet with exuberant cancer in this region.

PERSISTENCE OF EPITHELIOMATOUS DEGENERATION

There are cases in which an epithelioma is removed and the base treated by irradiation, but in which keratoses form on the scar, and under these keratoses in this new scar tissue epitheliomatous degeneration takes place. The scar may appear to be perfectly healthy and yet this type of degeneration continues, and it evidently does not come from the depth but always, as before mentioned, first arises on the surface as a keratosis. This is not the same as the condition called benign cystic epithelioma, which forms little cysts lined with epithelium and filled with a jelly, and which also shows an inveterate tendency to recur *in loco* in spite of anything that may be done, either operatively or by irradiation. In fact they are not at all influenced by irradiation. It is thought that these latter are in their nature nevi.

In operating, the psychic influence of the situation of a cancer is often most important. I once had an interesting experience with this source of error. A surgeon was removing a cancer from the side of the face. His line of incision took a wide sweep forward, unnecessarily wide, but as it came around in front of the ear it approached nearer and nearer to the tumor until directly in front of the ear it even slanted forward under it. One could see that he had in mind to avoid the ear and also the facial nerve. When the tumor was removed it was seen that he had cut through a cancerous nodule, half of which was left *in situ*. As this error was recognized, it was corrected, but it could easily have escaped notice. The surgeon was a well-educated, well-trained, experienced man, but the temptation to avoid entering troublesome ground acted almost subconsciously on his mind, and guided his hand.

IN CONCLUSION

The foregoing is a narrative of some of the traps that nature lays for us in dealing with a most treacherous disease. Cancer is an infiltrative disease and, therefore, naturally has no definite borders, and, knowing this, one must in treating it go beyond the visual border. Furthermore, epithelioma arises almost invariably on a degenerative skin and represents the high point in this degeneration. It is, of course, impossible to remove the whole skin, so this dangerous high point is the only portion removed. The remaining skin continues liable to the same form of degeneration. This is inevitable, but it gives rise to many misunderstandings between patient and physician.

These are some brief sketches of personal experiences with a most elusive affection, elusive because of its mimicry of other diseases leading to erroneous diagnoses, and also because it is infiltrative and, therefore, deceptive, as to the extent of the infiltration. And in addition to this cancer is a degenerative manifestation of a more general tissue malady and, while the individual lesion may be eradicated, yet the tendency continues.

DISCUSSION

Hiram E. Miller, M. D. (384 Post Street, San Francisco).—In a pleasing and informal way Doctor Montgomery has given us many interesting facts in regard to epitheliomata of the skin that are not found in textbooks. It is unfortunate that, under diagnosis, he did not differentiate between basal-cell and squamous-cell epitheliomata. They generally have such distinct characteristics,

I have not found in my experience that epitheliomata of the ear are "particularly liable to metastasis." They are generally of the squamous-cell type, and frequently remain without metastases for a year or more. This would be very unusual in any other location.

I did not have the impression that epitheliomas arising from the lining of sebaceous glands were mostly spinocellular in type. Those arising around a comedo or patulous follicle have practically always, in my experience, been of the squamous-cell type, but I assumed that they came from the surrounding epithelium or lining of the duct and not the gland itself. Many deep-seated basal-cell epitheliomas apparently arise from the sebaceous glands, sweat glands, hair follicles, etc.

The author has emphasized the occurrence of epitheliomata on degenerative skin, and the fact that it is impossible to remove the whole skin. This fact, however, should be explained to the intelligent patient to safeguard misunderstanding and to help him understand his disease.

* * *

H. J. Templeton, M. D. (3115 Webster Street, Oakland).—After a clinical diagnosis of cancer of the skin has been made, two important questions arise. First, what is the cell type of the malignancy—is it a basal-cell epitheleoma or a squamous-cell epithelioma? This is of far more than academic interest, for upon this point one must base his decision as to whether local destruction is sufficient, or whether he must consider removal of the glands draining the area involved. If the growth proves to be of the basal-cell type, thorough local destruction is sufficient. If it is of the squamous-cell variety, one must consider whether or not the degree of involvement calls for an attack upon the regional lymph glands by means of surgery or radiation.

Our procedure is to remove a piece of tissue, preferably from a non-ulcerated, non-infected area of the tumor by means of a deeply cutting, electrically driven punch. This tissue is examined immediately by frozen section if we feel that it is urgently required, but usually we believe that the delay of two or three days which is required for ordinary paraffin sections does not endanger the patient's chances. For, immediately upon completion of the biopsy, we destroy the local lesion quite radically.

The second question that arises when skin cancer has been diagnosed is in regard to what treatment should be given. Success in the treatment of skin cancer obviously depends upon the complete destruction of all cancer cells. This may be accomplished by several different methods or combination of methods. The choice of methods will vary with different cases. We believe that that method is best with which the individual operator is most familiar. Wide surgical excision, the actual cautery, electrosurgery, radium, or x-ray—all of these will cure most cases of skin cancer if properly applied. However, in the average run of cases we must confess a personal preference for methods of destruction, especially electrosurgery of the actual cautery, rather than radiation therapy. There are no cancers which are incapable of destruction by such means, while, on the other hand, it is well known that some cancers are not destroyed by conservative doses of x-ray or radium. True it is that radiation can be given in such heavy doses as to actually cauterize and destroy the cancer, just as effectively as an actual cautery does; but with such massive doses the normal tissue cells beyond the cancer receive such heavy doses of radiation as to be permanently damaged. This does not occur with electrosurgery or the actual cautery.

In stating this personal preference for destruction, as opposed to radiation therapy, we do not mean to imply that radium or the x-ray should not be used. We feel that they are invaluable, but that they should be employed in certain selected cases, or as an adjunct rather than routinely.

* * *

Arne E. Ingels, M. D. (490 Post Street, San Francisco).—With Doctor Montgomery's vast experience in his career as the pioneer in dermatology on the West Coast, I feel rather humble in commenting upon his most interesting article.

I would like to mention the fallacy of the strict classification of epitheliomas as basal-cell epitheliomas and squamous-cell epitheliomas.

The clinical appearance of a basal-cell epithelioma. with its waxy, transparent nodular and raised border may indicate a less radical treatment, since no classically listed basal-cell epithelioma has been known to metastasize.

However, I have seen a number of epitheliomas showing the clinical appearance of basal-cell epithelioma which histopathologically manifested themselves as the basal-cell, squamous-cell epithelioma type. I think the treatment should be radical, whatever means are preferred, if a biopsy is not taken.

Secondly, I shall mention the superficial epitheliomatosis: the slowly advancing, almost imperceptibly raised border, may leave a slightly atrophic or normal looking surface. The less experienced will easily confuse these with eczematous patches or lupus erythematosus, and treat them as such. Keeping in mind that they actually may represent a mixed basal-squamous cell epithelioma, they require the radical treatment as much as the clinically more conspicuous ones.

Doctor Montgomery's mentioning the benign epitheliomas of the skin is essential for the understanding of the genesis of the epitheliomas. Modifications of the normal basal-cell layer develop into the intermediary benign epitheliomas as the epithelioma adenoides cysticum-syringoma-cylindroma group with further developments into the extremes, the clean-cut malignancies and their anaplasias.

* * *

Doctor Montgomery (Closing). — The remark that my paper does not include more on the subject of cancer is an unexpected pleasure, as it assures me that it is not tedious. I am reminded of Voltaire, who said that all writing is good, provided it is not wearisome. And the great French satirist did not leave you in doubt as to what he meant by wearisome, since he added, "If you wish to be wearisome, say it all." In fact I need not add that there is a good deal more to be said about epithelioma than is contained in my paper.

Regarding the differentiation between squamous- and cuboidal-celled epitheliomas, I think it was Darier who first strongly accentuated this distinction; but that eminent pathologist soon found that the distinction was not so simple, and shortly afterward my primary enthusiasm was dampened by the examination of a band-like growth across the lip which at one end was cuboidal- and at the other squamous-celled. About this same time a well-known dermatologist made the sweeping assertion that all epitheliomas of the exposed red of the lower lip were squamous-celled, which is not so. And, by the way, sweeping assertions are apt to be erroneous.

As for biopsies, if possible a diagnosis should be made without resorting to them. A biopsy to be thoroughly effective should include some of the normal tissue beyond the border of the lesion. This of course increases the scar, and the extent and nature of the scar resulting from annihilation or extirpation of an epithelioma is frequently a grave matter. The cicatrix resulting from any operative procedure should be as pliable and smooth as possible, not alone because of its cosmetic effect (and this is important), but also because a bad scar is more apt to degenerate into cancer than a good one. The subject of the liability of scars to cancerous degeneration is important, and sometimes disregarded. One of the great advantages of correctly applied radiant energy is the beneficial effect it has on the formation of the scar following the operation.

CHEMOPROPHYLAXIS OF POLIOMYELITIS[*]

(A PROGRESS REPORT)[†]

By E. W. SCHULTZ, M.D.
AND
L. P. GEBHARDT, M.A.
Stanford University

THAT the olfactory nerve is the common portal of entrance of poliomyelitis virus is now well established: Schultz and Gebhardt, 1934;[1] Brodie and Elvidge, 1934;[2] Lennette and Hudson, 1935.[3] It is also clear from recent experimental studies that the administration of specific immune serum does not afford significant protection against subsequent intranasal instillation of monkeys with poliomyelitis virus: Schultz and Gebhardt, 1935.[4] The failure of immune serum to afford protection against instranasally-inoculated virus may be explained by the fact that the terminals of the olfactory nerve are so situated that they cannot be effectively guarded by immune plasma, and further explained by the fact that virus once established in the olfactory or other nerve tracts is, for the most part, safely out of reach of humoral antibodies. It has, moreover, been quite conclusively shown that the injection of poliomyelitis vaccines, at best, results in the production of humoral antibodies, with no recognizable increase in tissue resistance, or significant protection against virus administered by the intranasal route: Schultz and Gebhardt, 1935;[5] Olitzky and Cox, 1936;[6] and Hudson, Lennette and Gordon, 1936.[7] These observations seem to leave little prospect of a practical solution of the poliomyelitis problem by orthodox means. It has become necessary, therefore, to seek a solution in new directions.

RECENT STUDIES REPORTED IN THE LITERATURE

In 1934, Olitzky and Cox[8] made the interesting observation that a dilute tannic acid solution in distilled water, dropped into the nostrils of white mice three times a day on three successive days, served to protect these animals against intranasal instillation of equine encephalomyelitis virus administered on the fourth day. The protection afforded was transient, since it disappeared almost completely by the tenth day. Soon after, Armstrong (1935)[9] made similar observations on experimental St. Louis encephalitis in mice, using sodium alum as the protecting agent.

AUTHORS' STUDIES

Without being aware of these latter interesting observations, we undertook, in the spring of 1935, to test the possibility of protecting monkeys against intranasal infection with poliomyelitis virus by chemical means. We first tried tannic acid; but finding the results of two experiments somewhat irregular, we turned our attention to picric acid and certain other agents. Soon after (May 31, 1935), Armstrong and Harrison[10] reported that monkeys which had previously received intranasal treatment with 4 per cent sodium aluminum sulphate, exhibited a high incidence of protection against subsequent intranasal instillation of virus. The duration of the protection was not determined. Several months later, in January, 1936,[11] these observations were confirmed by Sabin, Olitzky and Cox, who found that 4 per cent tannic acid also afforded temporary protection. On February 5, 1936, we[12] reported to the Pacific Coast Section of the Society of Experimental Biology and Medicine observations which indicate that protection is also afforded by picric acid, p.-nitrophenol, trinitrocresol and by mercurochrome. These observations showed that the protection afforded may, in some instances, be of several months' duration. Late in the same month (on February 28) a paper by Armstrong and Harrison[13] appeared, dealing with further studies on chemical protection of mice against intrasanally-instilled St. Louis encephalitis virus, and with the protection afforded monkeys by picric acid against intranasally-instilled poliomyelitis virus. Although they made no observations on the actual duration of the protection afforded, and their technical procedures were not altogether like ours,[‡] the results were essentially the same.

SUMMARY ON THE AUTHORS' OBSERVATIONS

We wish at this time to present a summary of our observations to date, and to indicate the possibilities offered by further investigations in this field.

Of sixteen monkeys given three successive daily intranasal irrigations with 1 per cent aqueous solution of picric acid, only three animals succumbed to intranasal instillations of 10 per cent virus suspensions (three instillations on one day) administered one to eight days following the treatment; one of those developing poliomyelitis had been given intranasal washes with saturated aqueous lithium carbonate, in an effort to remove the picric acid from the nasal mucosa. Of the thirteen monkeys which survived, ten escaped a second instillation of virus administered eighteen to thirty-nine days after treatment; the three which became infected received the virus instillations twenty-seven, thirty-one and thirty-nine days after treatment with picric acid. Only eight of the survivors have been tested further. Of these, five escaped a third instillation of virus administered forty to sixty-eight days after the treatment. Of the remaining five animals, two out of three which had gone sixty days, developed poliomyelitis after a fourth instillation of virus. One resisted nasal virus seventy-three, ninety-four, 108 and 129 days and one eighty-nine days after the original treatment. One of the latter two died of an intercurrent infection 110 days after the original picric acid treatment; the remaining animal withstood a

[†] These studies were supported by a grant from the President's Birthday Ball Commission for Infantile Paralysis Research.

[‡] The monkeys are deeply anesthetized, placed in a vertical position, and the nasopharynx thoroughly irrigated with about 30 cubic centimeters of the chemical.

fifth intranasal instillation of virus ninety-two days after treatment, but developed poliomyelitis after a sixth virus instillation 121 days after the treatment with picric acid.

Of six monkeys treated with three nasal washes of 1 per cent picric acid neutralized to pH 6.9, three failed to resist inoculation ten days after the third treatment. Two of the remaining three monkeys have further resisted inoculation thirty-one and fifty-five days after treatment, while one died of tuberculosis seven days after the second virus inoculation. Each picric acid wash was preceded by a nasal spray of 0.25 per cent neosynephrin.

In still another experiment twenty monkeys were given intranasal sprays with 1 per cent picric acid in physiological saline solution on three successive days and thereafter once a week. Virus instillations were begun one day after the third treatment and continued daily, with the exception of the days on which the picric acid treatments were administered. This has to date been carried on for a period of about three weeks, with the result that nine of the ten controls used have developed poliomyelitis, while only six of the twenty animals treated have come down with the disease. The daily virus instillations and weekly treatments with picric acid are being continued with new sets of controls.

ON THE RELATIVE EFFICACY OF REPEATED WASHINGS

Observations on the relative efficacy of repeated washings with lower concentrations of picric acid are too limited and irregular to justify detailing here.

Of a total of thirteen monkeys given three successive daily nasal irrigations with 2 per cent aqueous solution of mercurochrome (No. 220 solution), one only developed poliomyelitis following intranasal instillation of virus administered two to six days later; one died of an intercurrent infection twenty-five days later; of the eleven remaining animals all have resisted intranasal instillation of virus twenty-three to thirty-one days after the treatment (one died of an enteritis twelve days, and one of tuberculosis two days following the second virus inoculation). The remaining nine animals were given a third instillation of virus on the thirty-eighth to fifty-second day after treatment (one died later of tuberculosis and one of enteritis). One only developed poliomyelitis. The remaining six monkeys were inoculated again fifty-eight to seventy-nine days after treatment. This time two developed poliomyelitis (one given virus fifty-eight and one seventy-three days after treatment). One died of enteritis two days after inoculation. (It might be well to note that the majoriy of the animals are observed from twenty-one to thirty days before each reinoculation with virus).

Of twelve monkeys which had been given intranasal irrigations with 1 per cent mercurochrome on three successive days, ten resisted intranasal instillation of virus one to eighteen days later. These two developed the disease when inoculated eleven days after treatment. One died twenty-two days later of an intercurrent disease. The remaining nine monkeys were reinoculated thirty-one to sixty days after treatment. One inoculated thirty-two days and one fifty-three days after treatment developed the disease, while one died of an enteritis two days after the third virus inoculation. Of three animals which had been given the mercurochrome (1 per cent) by simply dropping 2 cubic centimeters of the dye into the nostrils once a day on three successive days, only one developed poliomyelitis when tested eleven days after the third dye wash. The remaining two monkeys have resisted nasal virus thirty-two, fifty-three and seventy-seven days, respectively, after the original treatments.

Seven out of seven treated monkeys resisted virus when tested ten days after they were treated on three successive days with 1 per cent mercurochrome (phosphate-saline pH 8.6). These seven monkeys were reinoculated thirty-one days after treatment, and this time two animals developed the disease. These monkeys received a nasal spray of 0.25 per cent neosynephrin one-half hour before each mercurochrome wash.

Five monkeys received a similar treatment (but without neosynephrin) with 0.5 per cent mercurochrome and virus given nasally eleven days after the third dye treatment: three developed the disease: one died of an enteritis on the tenth day, and one survived the virus inoculation. This surviving monkey has further resisted nasal virus thirty-two and fifty-three days after the original mercurochrome treatment. Of six monkeys receiving three successive daily nasal washes with 0.5 per cent mercurochrome (phosphate-saline pH 8.6) and sprayed nasally with 0.25 per cent neosynephrin one-half hour before each dye treatment, only one developed the disease when inoculated ten days after the above treatment. One of these animals died of an enteritis three days after the virus inoculation. The remaining four animals were reinoculated thirty-one days after treatment, and this time two developed the disease. Three other monkeys were given three successive daily nasal washes with 0.25 per cent mercurochrome, and then given virus nasally two days after the third dye treatment; all three developed the disease.

EFFECTS OF OTHER CHEMICAL AGENTS

The effects of a number of other chemical agents have been less extensively studied. Four monkeys given intranasal washes with 1 per cent aqueous paranitrophenol resisted instillations of virus two to seven days after treatment. Three resisted a second instillation of virus thirty-one to thirty-nine days after treatment, while one developed poliomyelitis when inoculated thirty-one days after treatment, and one died with an enteritis eighteen days later. The two remaining animals resisted a third instillation of virus administered fifty-two days after the treatment. One, however, succumbed to poliomyelitis following a fourth instillation seventy-three days after chemical treatment and one died of tuberculosis twenty-nine days after the fourth instillation of virus.

Of three monkeys treated with a 0.5 per cent aqueous solution of paranitrophenol one resisted an instillation of virus two days later; one developed typical poliomyelitis, while one died of an enteric disturbance nine days after inoculation. When a further test was carried out twenty-three days after the treatment, the one monkey remaining developed typical poliomyelitis.

More or less long protection also seems to be afforded by 1 per cent trinitrocresol; by 1 per cent silver nitrate (two monkeys protected two, twenty-three and forty-four days); by 5 per cent protoargentum; by 10 per cent argyrol; by 2 per cent erythrosine; by 1 per cent neutral acriflavine; by 1 per cent zinc sulfate (three monkeys protected two, twenty-three, forty-four and sixty-eight days).

Three monkeys were protected by 1 per cent thionin for at least twenty-three days; two of these died of an enteritis, one twenty-one days and one twenty-two days after the second virus inoculation. The remaining monkey has resisted virus inoculation forty-four, fifty-eight and seventy-nine days after the original thionin treatment.

Three monkeys treated with 0.5 per cent thionin resisted virus instillation two days later. One died of an enteritis twenty-nine days after the virus inoculation. The two remaining monkeys have resisted inoculation twenty-three, forty-four and sixty-eight days after treatment.

Little or no protection was afforded by 1 per cent ammonium picrate, 1 per cent congo red, 1 per cent trypan blue, 1 per cent sodium fluorescence (uranin), 1 per cent trypan red, 1 per cent eosin yellowish, 0.25 per cent mercurochrome or 10 per cent normal monkey cord.

IN CONCLUSION

It is apparent that the protected animals eventually will develop the disease in the absence of continued chemical treatment, provided the virus inoculations are continued for a sufficiently long period of time.

A total of 112 controls served in carrying out these studies, 84.8 per cent of which have developed poliomyelitis.

While various chemical compounds are more or less effective in protecting monkeys against intranasal inoculation with poliomyelitis virus, it does not follow, of course, that all of these are equally applicable to man. Of those we have studied thus far, 1 per cent picric acid in physiological saline seems in general the most suitable; not only because its effectiveness has been quite definitely established, but also because it is, in itself, essentially harmless and comparatively nonirritating. We would suggest that the solution be applied with an atomizer on three successive or alternate days, and thereafter once every week or ten days during the period of an epidemic. Since the solution should be thoroughly applied to the olfactory area, it is desirable to have the treatments carried out under the supervision of a competent nose and throat specialist, who would consider the anatomic conditions which might ordinarily interfere with making the necessary contact with this area.

HEAT PRODUCING APPLIANCES: THEIR COMPARATIVE VALUE IN THE TREATMENT OF PROSTATIC INFECTIONS*

By James B. Herring, M. D.
San Francisco

Discussion *by Norman N. Epstein, M.D., San Francisco; Robert V. Day, M.D., Los Angeles.*

RAISING the temperature of the prostate has therapeutic value. I believe most, if not all of us, will subscribe to that statement. It leaves only the question as to what is the best method of producing the heat.

METHODS OF TREATMENT

The fact that there are so many types of treatment is evidence that a satisfactory method has not been evolved. Massage, irrigation, dilatation and posterior urethral instillations have been used, but with varied and not entirely satisfactory results. Vaccines, injections of various types, and numerous appliances have been employed. The keystone has been digital massage, a thoroughly unscientific procedure, but so far, the best. Acceptable conclusions, however, have never been reached, because they have been based on "cure," and the time consumed in producing cure, when we have no entirely agreeable method of determining when cure has been produced.

METHODS OF DETERMINING CURE

By signs.—Examining prostate rectally, most of us feel, is unreliable. Tenderness and, especially, induration, are probably the best signs, but influenced too much by a patient's neurogenic make-up. Urethroscopic examination is of some advantage, but few could use it as a method of determining when a prostate is healed. This leaves only microscopic examination of expressed fluid upon which we may base our conclusions; but here figures are only arbitrary, each teacher having his own standard.

---

* Read before the Urology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

By symptoms.—A patient will draw conclusions of cure from his freedom of symptoms, but a practitioner who bases scientific conclusions on statements which are so easily produced by psychic reactions, is treacherous to the principles of his profession.

The term "cure" can offer no basis for proof of therapeutic virtue. Definition of what is meant by "cure" varies widely in the minds of different men. A case considered cured by one man would still be under treatment by another. Unfortunately, prostatic massage is painful. Some urologists being too gentle, fail to squeeze pus from the obstructed prostatic tubules, and consider the patient cured, while others would find pus in the case. This causes a disagreement as to time required for treatment, some saying that three months should be sufficient, while others say six years to life.

This unreliability of established cure has allowed us to drift away from facts. It has increased our susceptibility to colorful statements of manufacturers and salesmen of all manner of prostatic machines, and has produced a gullibility that gives credence to testimonials from any and all sources. This is well demonstrated in articles about the Elliott machine found in the *Ladies Home Journal, Country Gentleman* and outstanding medical periodicals.

Therefore, to avoid these errors, we should discard second hand conclusions and go back to first principles of scientific research. Raising the temperature of the prostate has definite therapeutic value. The value of any type of heat-producing equipment must not be judged by its ability to *cure*, but only by its ability to *produce heat.*

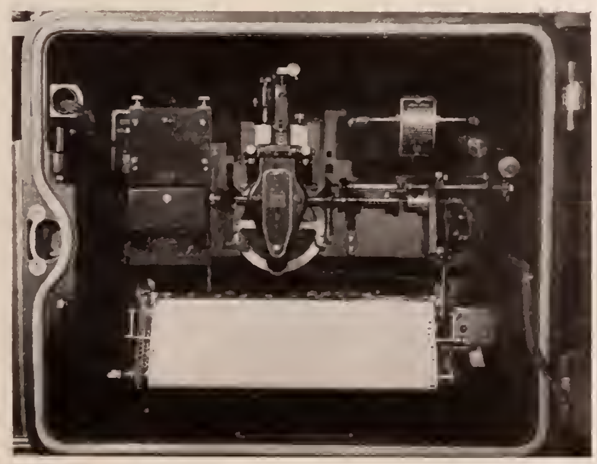

Fig. 1.—A Leeds and Northrup temperature recorder with Micromax mechanism.

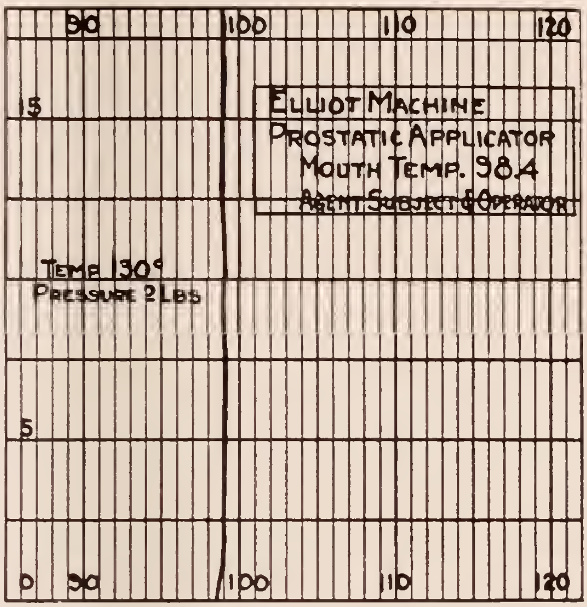

Fig. 2.—An Elliott machine salesman treats himself for prostatic infection; maximum temperature in the prostate, 99 degrees.

I will demonstrate this last fact by charts. These charts have been constructed by a curve-drawing potentiometer connected to a thermocouple placed in the posterior urethra during treatment. The recording device is guaranteed accurate to three-tenths of a degree Fahrenheit. The charts are consequently free from error, either mechanical or such as might be due to the "personal equation," for there are no readings made by the operator.

HOT WATER THERMAPHORE

This familiar instrument has been used for generations, and still is widely used in nearly every hospital in the country for the treatment of painful prostatic conditions associated with swelling. We found that the water, at 122 degrees, was sufficiently hot to burn the rectum, but not to change the temperature in the posterior urethra. Consequently the relief of pain when obtained by *this* method must be due to the effect of counter-irritation.

THE BRANSFORD-LEWIS HEATER

This instrument is an infra-red type of prostatic heater. A study of the chart shows that if there is any effect from its use, other than counter-irritation, then it must be psychic therapy, for there is no more rise of temperature in the prostate than might be produced by a mustard foot-bath. In order to check the recording device, diathermy was applied, and the rise in temperature demonstrated that at least the recording device was working.

ELLIOTT TREATMENT

The utter simplicity of a chart made while using this machine should, perhaps, be explained. It is the graph recorded when what should be called the Elliott Motorized Hot Water Bag was used. If you fail to see any appreciable variation in the

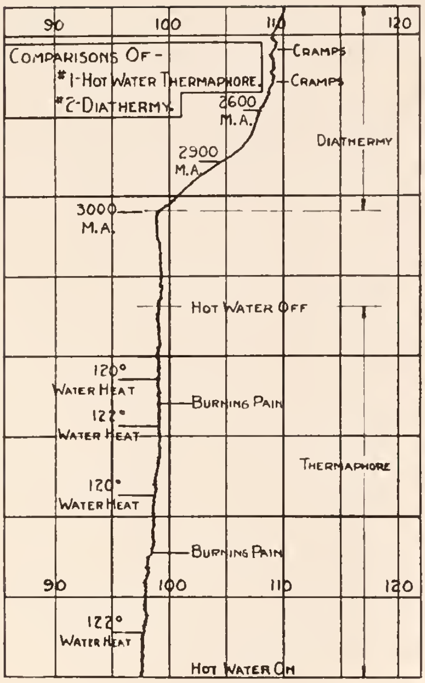

Fig. 3

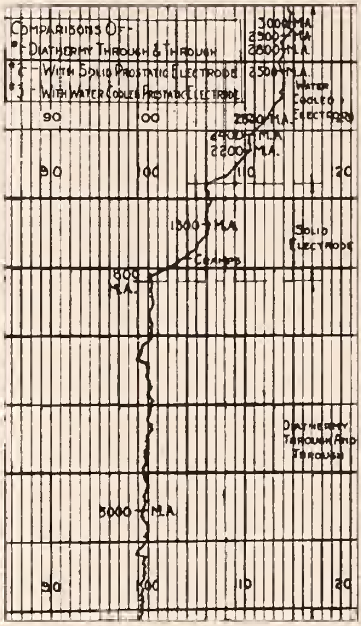

Fig. 4

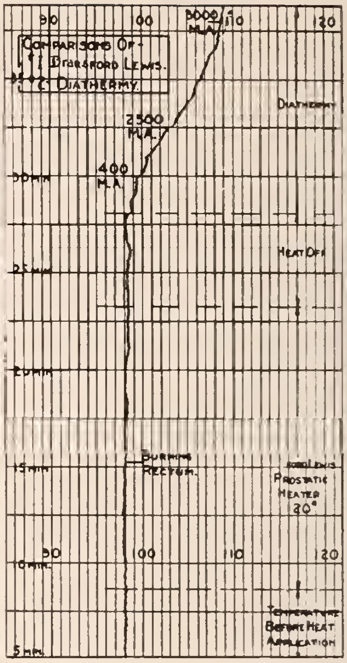

Fig. 5

Fig. 3.—Comparative temperatures obtained with a hot water thermaphore and diathermy used successively on the same patient, 99 degrees and 109 degrees respectively.

Fig. 4.—Diathermy treatment of the posterior urethra. With ordinary rectal electrode a temperature of 107 degrees was recorded; with a water-cooled electrode the heat was increased to 115.5 degrees.

Fig. 5.—The Bransford-Lewis prostatic heater raised the temperature in the organ only a fraction of a degree. Diathermy applied to the same patient produced 109 degrees.

line drawn by the recording instrument, it is because there was no change in heat.

In thirty minutes' time the temperature rose to 98.5 degrees. In view of the fact that the representative of the manufacturer gave this treatment to himself, the method cannot be at fault. He had told hundreds of doctors that by the use of this equipment he had cured his prostatic infection. However, a check which I made on his condition demonstrated an acutely infected prostate existing, causing me to doubt the completeness of his self-styled cure. Another example of how false conclusions are often based on supposed cures. I wonder how many of the other advertised Elliott cures are of the same type!

CONCLUSIONS CONCERNING HEAT BY CONDUCTION

That heat cannot be conducted through living tissues in appreciable amounts is demonstrated by these charts. Although the temperature in the rectum was raised to the tolerance of the rectal mucosa, there never was demonstrated any temperature rise in the posterior urethra.

Caulk applied on actual cautery to living tissues and found that it required nine seconds or more to produce any heat at a depth of as little as four-tenths of a centimeter. My own observation invariably has been that human tissue is a mighty efficient insulator.

RADIO FREQUENCY

Radio frequency was used in an attempt to heat in a condenser field. An insulated electrode was inserted in the rectum with a condenser-pad externally applied, and was found to be absolutely impractical because of the intense heat produced within the orificial electrode itself, almost immediately burning the rectal mucosa.

When two condenser pads were placed externally, it was possible to show an elevation of about one degree. We used seven different makes of apparatus to conduct these experiments, and arrived at the same conclusions as Bernard Mortimer and Stafford L. Osborne, who recently reported that three out of six machines tested were worthless. Using thermocouples in internal organs, they found that organs outside of the condenser field heated to the same degree as others within the field; also that there was a gradient of temperature from the skin inward even more marked than when ordinary diathermy was used—a fact which our experiments corroborated.

I believe that time will demonstrate that radio frequency is to be compared with ordinary diathermy, its only advantage being its possible ease of application, while its disadvantages will be those of increased difficulties in localizing its effects because of increased voltage.

ADAPTATION TO PROSTATIC HEATING

There is a way, however, to adapt radio frequency to prostatic treatment, making it compare favorably to diathermy. If the usual bare type of orificial electrode is inserted in the rectum without insulation, and this electrode is connected to one side of a condenser of proper capacity (the other side being connected to the radio frequency machine), then with the usual insulated pad placed on the abdomen, the treatment may be given effectively, concentrating the heat where it is desired.

DIATHERMY

The first portion of this chart records temperatures produced by diathermy in the posterior urethra with pads over the buttocks and over the lower abdomen, using as much as 5,000 milliamperes of current. There is practically no indication of deep heat. The second portion shows that by using a rectal prostatic electrode of the usual type, a temperature of 106 degrees was reached. In the final section of the chart the unusual is seen. The highest temperature ever recorded in the living human body was when the recording needle drew the temperature line well above the 115 degree marker. In order to produce locally this high temperature with diathermy, I found it necessary to design a special rectal electrode which is water-cooled, thus allowing an increase of 50 per cent in the amount of current used. In practically every patient treated, we have been able to produce a temperature of from 109 to 112 degrees, and maintain it for as long a time as desired.

CONCLUSIONS CONCERNING HEAT BY HIGH FREQUENCY CURRENTS

Radiothermy is, in our experience, merely a less efficient form of diathermy, and must be localized with orificial electrodes to produce local effects.

Diathermy as well as radiothermy has little deep effect when given with external pads or condensers. Either one applied with orificial electrodes will heat the prostate, the temperature increase being limited by the tolerance of the rectal mucosa.

When a water-cooled electrode is used, diathermy increases prostatic temperatures up to the tolerance of prostatic tissue. Since the electrode remains cold, the tolerance of the rectal mucosa is no longer a factor.

In general hyperpyrexia authorities agree that a temperature of from 106 to 107 degrees for three hours is necessary to obtain results which seem to be due to the action of the heat itself directly on the invading organism. Many have felt that improvement was due to some vague systemic change producing immune bodies in the tissues. This theory has never been substantiated, and that it is in error, on the other hand, has been demonstrated to the satisfaction of most clinicians.

The blood of a hyperpyrexia patient has not been shown to possess any increase in specific resistance. Epstein and Cohen have established abundant proof that it is the actual temperature for a definite time interval that brings about the death of the Treponema pallida, whether in the test tube or in the body tissues. They reported a case of generalized maculopapular eruption with moist papules over the vulva, mucous patches in the mouth and infiltrated papules over the forehead. All the lesions except those on the forehead cleared rapidly under fever treatment. This phenomenon is not unusual and is easily understood when we realize that the skin of the face remains relatively cool during any type of fever therapy.

In view of the fact that the greater part of the good effect obtained from general hyperpyrexia comes from the temperature itself, it is not necessary to raise the temperature of the entire body in order to treat pelvic conditions. We can raise local temperatures by methods just given and maintain them with safety. This safety factor is important when, in our own vicinity, there have been two deaths due to general hyperpyrexia.

SUMMARY

Such appliances as hot water irrigators, the Elliott machine, and other infra-red generators used to heat by *conduction,* fail to produce heat in the prostate. On the other hand, high frequency, ultra high frequency, or ordinary diathermy, with proper orificial electrodes, are of value, and the greatest elevation of temperature is obtained with the use of a water-cooled electrode.

490 Post Street.

DISCUSSION

Norman N. Epstein, M.D. (450 Sutter Street, San Francisco).—Doctor Herring has suggested an excellent method of producing high temperatures locally within the prostate. As my knowledge of prostatic infections is limited, I shall confine my discussion to the subject of general hyperpyrexia. The production of general hyperpyrexia is a much different problem from the elevation of the temperature of tissues in a localized area. An artificial fever can be produced by preventing radiation of heat from the body surface through simply wrapping the patient carefully in blankets and adding some source of external heat. Using this method, it was observed that the general body temperature rose gradually to the desired height—that is, from 104 degrees Fahrenheit to 106 degrees Fahrenheit.

The exact mechanism through which artificial fever produces therapeutic results is not entirely known. There are probably several factors involved. There is a direct effect upon the causative organism and an effect also upon general body and tissue resistance. There may be other effects which at present are not fully understood.

While it is logical that general hyperpyrexia should be used only in systemic infections, yet it may be of value in certain local pathological processes. We observed that general hyperpyrexia was of great value in the treatment of gonorrheal arthritis limited to one or two joints. Beneficial results have been reported on the use of artificial fever in gonorrheal urethritis. Further work is necessary to determine whether general hyperpyrexia is of value in the treatment of prostatitis and other infections of the genito-urinary tract.

⁂

Robert V. Day, M.D. (1930 Wilshire Boulevard, Los Angeles).—It is a delight to be able to read and review such a sound exposition of this subject, backed up by comprehensive clinical observations and checked by reliable physical methods of precision. There has been nothing left to guess-work or personal equation, wherever this has been avoidable. Doctor Herring's report tells us authoritatively just what heat effect we may expect from each type of machine or apparatus in the way of producing a rise of temperature in a more or less localized and circumscribed area.

Just what and how much may be accomplished by the application of heat to a given area, is the subject of considerable controversy. Every clinician has observed its benefits in a certain percentage of inflammatory conditions, especially in the presence of inflammatory exudate. Whether or not it is the best practice to start the heat treatment prior to the peak or crest of the inflammatory process, is perhaps debatable. Certainly, however, there comes a time when localized heat hastens resorption of inflammatory exudates and promotes natural drainage through excretory ducts, provided that the trauma incident to the application of heat therapy does not counterbalance the benefit. Specifically, I mean that with a fairly acute prostatitis where the tender inflamed prostate bulges well into the rectum, the introduction of an electrode well up into the rectum often produces much local distress, to which the physician all too often pays not the slightest note, having previously made up his mind that it possessed great therapeutic merit and should be employed regardless of the fact that ofttimes it is severe punishment to the patient and tends rather to retard than to hasten a cure. Even the hot water thermaphore often causes great discomfort in cases where the bulging prostate is much pressed upon. Manipulation of, and pressure on, an acutely inflamed prostate is just as illogical as squeezing or pressure on a tonsil in a patient with acute follicular tonsillitis, and in practice a really intelligent patient resents any kind of pressure or manipulation on an acutely inflamed prostate. All these electrodes are almost certain to do just that.

With chronic conditions heat locally applied may be of considerable value; but, after all, it is only one factor in the therapeutic management. Certainly no one has brought forth any worth while evidence that the beneficial effects of heat in this area is the result of any bactericidal action of heat. Obviously such notions are only the result of wishful thinking. While the beneficial effects are undoubted, this is effected in all probability through hyperemia, the hastening of absorption of exudate, promotion of drainage through the ducts, both by reason of the hyperemia and the pressure of the electrode on the prostate.

My more limited clinical experience tends to exactly bear out Doctor Herring's conclusion as to the comparative efficiency of the several types of machines. Doctor Herring, in passing, refers to the criterion of cure. I should like to emphasize that such criteria should always be based on every fact relative to a given case, including subjective symptoms, physical findings and laboratory data.

Finally, the local application of heat to the prostatic area is only one of the various agents of proven value in the treatment of inflammations and infections of the prostate and seminal vesicles. The great criticism, concerning many types of physiotherapy, is that their advocates too often manifest an altogether too exaggerated notion of their efficiency, to the neglect of other proven and recognized forms of therapy. Heat at best, no matter how applied, is only an adjuvant, not a cure-all. If we recognize its limitations as well as its great value, and prescribe it intelligently without expecting miraculous results to follow in every case, and at the same time display judgment in the selection of machines, such as Doctor Herring has done, we may give much satisfaction to our patients and ourselves by its employment.

A Final Warning.—Only in the occasional case which fails to respond to more moderate measures, should we resort to ultravigorous massage or an extreme degree of heat to the region of the prostate. Otherwise, there will be many flare-ups resulting in subacute prostatitis and even epididymitis, sometimes becoming quite acute. Clinically such observations are not infrequent. One should resist a certain human tendency to argue that if a little is good, more is better!

⁂

Doctor Herring (closing).—We are in full accord with Doctor Epstein's statement that the mechanism of producing therapeutic results in artificial fever is not known. Recent work, however, more and more is tending to prove that it is the heat alone that produces the therapeutic results, and not some vague unknown secondary factor. Based on this conclusion, I have been applying heat in known amounts to local parts.

I appreciate Doctor Day's appraisal of the work as outlined in my paper. I agree with him that acute conditions of the prostate should not be handled by rough massage and unknown quantities of heat. It was because of this fact that I designed an electrode shaped and water-cooled to minimize traumatization, and have recorded temperatures so that no haphazard procedure need be employed to an organ so susceptible to violent adverse reactions. Under these controlled conditions I have had no complications, and have not hesitated to treat a prostate with heat, in the face of most acute infections. However, I should say here that in the acute stages of gonorrhea, I do not use this method.

CLINICAL STUDIES WITH PROTAMINE-INSULIN

By Bertnard Smith, M.D.
Los Angeles

INTRODUCTION.—A large amount of investigative study in the last ten years has been directed to the problem of slowing the rate of insulin absorption after injection into the subcutaneous tissues. This work has been stimulated by the difficulties found in maintaining a satisfactory control in many diabetic children, and in diabetic adults of the more severe forms, where blood sugar values may range in twenty-four hours from a dangerously low figure to an extreme hyperglycemia. The first evidence of possible success in solving this problem was in the reports from the Steno Memorial Hospital of Copenhagen [1] on the studies with protamine insulinate, and the later publications from the same institution [2] and from the George F. Baker Clinic of Boston.[3]

PROTAMIN BUFFER: METHOD OF HAGEDORN OF COPENHAGEN

Early in this year the Eli Lilly Company began supplying a preparation of iletin with protamine buffer, using in preparation the methods of Doctor Hagedorn of Copenhagen. This protamine-insulin is distributed for clinical studies with the same generosity, and in the same spirit, as was shown by this company in 1922 with insulin. This report is concerned with clinical observations on twenty-five diabetic patients who have been using the Eli Lilly protamine-insulin for sufficient time to justify some conclusions as to the early effects. The results of similar studies have recently been published by Dr. R. M. Wilder,[4] of the Mayo Clinic, Dr. E. P. Joslin,[5] and Kerr, Best, Campbell and Fletcher [6] of Toronto.

REPORT OF CASES

Cases 1 and 2.—The first patients selected for the studies now presented were two children, twin sisters, with the onset of diabetes in January and October, 1931. Both have been under observation in this clinic since diabetes was found. Both have been frequently hospitalized in the five years for acute complications. One had eleven admissions in five years and the other thirteen. Both had been taking diets of the same values, for a number of months before this study was begun, with insulin given four times in each twenty-four hours. These patients were held in the hospital for three months, with daily urine analyses and frequent blood sugar studies. Table 1 gives some of the significant results of urine analyses for the collection periods. In this table the designated day indicates the interval following change in dosage of regular insulin (R-I) or of protamine-insulin (P-I).*

Chart 1 shows a comparison of the blood sugar curves with regular insulin and with protamine-insulin. Curve 2 was obtained soon after an acute head cold, and before the morning dose of protamin insulin had been reduced to 20 units. The sister of this patient has had a record so similar as to make any detailed report almost a duplication.

Acute complications and breaking diets can cause sharp loss of diabetic control in both patients, but the even control possible with the protamine-insulin gives greater possibilities for increased resistance to infections and better possi-

---

* For convenience, regular insulin in this report is designated as R-I, and protamine-insulin as P-I.

bilities for normal development than could be secured with such blood sugar curve as seen in 1 of the chart. In the summary of urine analyses of Table 1, protamine-insulin given at 3:30 p. m. does not give as satisfactory control of glycosuria as does the 4:30 time. The same is true when the protamine-insulin was given at 6 p. m. When all regular insulin was stopped and protamine-insulin was given twice daily, there appeared definite increase in glycosuria and urine volumes when the interval between morning and evening doses was changed. The best control was manifest when injections were given from eleven to twelve hours apart. When this interval between injections was observed, the meal times for breakfast and supper were changed, and no increase in glycosuria occurred when protamine-insulin was given before, with or after the morning and evening meals. In all other patients who have been taking the protamine-insulin it has been routinely advised to fix a definite time for the injections with a twelve-hour interval, with the morning and evening meals within an hour before or after taking the insulin.

ON DISTURBED CONTROL

Table 1 also indicates the disturbed control that frequently follows the change from regular insulin to protamine-insulin and the increased glycosuria that may persist from two to ten days after even slight changes in the time of protamine-insulin injections. This sensitiveness appears to be much more pronounced in those patients who have been using regular insulin for some time than in new or mild diabetic patients who have never taken insulin. It is possible that a glycogenic function that has become somewhat adjusted to the more acute effect of regular insulin may be slower in adaptation to the more gradual effect of the protamine preparation.

REPORT OF CASES

Case 3.—Chart 2 shows blood sugar curves in an adult patient at the beginning and the end of a hospital study of three weeks. The tolerance gain is marked for this short time, especially when it is known that the patient entered the hospital before full recovery from an acute ketosis. Diabetes was of seven years' duration and control has always been very irregular. Full control is main-

tained since this patient left the hospital. Table *2* again shows the increase in glycosuria that immediately follows any change in insulin, either in unit dosage or time.

The clearing of marked periodic fatigue and improved endurance in the ten days since discharge from the hospital are mentioned by the patient as marked change in symptoms. There is evident improvement in nervous stability and this is probably due to the more evenly maintained blood sugar.

* * *

Seven patients with some cardiovascular complication are included in this group. In all of these the cardiovascular condition developed from one to fifteen years after the onset of diabetes. The ages of the seven patients range from 52 to 75 years. All have required insulin for several years, and diabetic control has been impossible even when insulin was given from three to six times daily.

ON INCREASE OF GLYCOSURIA WITH INSULIN CHANGE

An increase in glycosuria with each insulin change is seen in Table 3. This appears to clear as gradually in a patient of seventy-two years as in a patient of eight and one-half years. The afternoon dose of protamine-insulin was taken after the evening meal during the time this patient was in the hospital, which is the time covered by the data of Table 3.

COMMENT ON PATIENT GROUPS

Three patients of the seven with cardiavascular complications were able to hold full diabetic control on one dose of protamine-insulin, when regular insulin had been taken in two to four doses previously. Loss of early morning or late afternoon fatigue, increased general strength and clearer vision are symptoms most frequently given by this small group after the change from regular insulin to protamine-insulin. Some reason for this is seen in the blood sugar values as follows:

Age 70. Diabetes since 1932. Angina since 1935. Diet: C. 150, P. 60, F. 100.

After one month on protamine-insulin with dosage sixteen units morning and twelve units afternoon. Former regular insulin, 20-6-12-8.

	175	188	172	168

One patient who went to work after school was out in June had to change his routine of meals and protamine-insulin injection time. Working from 3 p. m. to midnight required him to have breakfast late each morning and supper at 1 a. m., after returning from work. He had been taking protamine-insulin twice daily and had held a fairly even diabetic control when attending school. Night-frequency returned and also high blood sugar values with glycosuria of high percentage. By taking regular insulin at 1 a. m. and protamine-insulin at 9:30 a. m. before breakfast, he has been

able to maintain satisfactory control and continue at work. This patient had night polyuria that lasted for about twelve hours after he first began taking protamine-insulin. Another patient, age twenty-four years, had a sharp ketosis immediately following the first dose of protamine-insulin. This cleared completely in about fourteen hours without any additional insulin. Three other patients have had acute diabetic symptoms for twelve to thirty-six hours after the first injection of protamine-insulin, and all have lost these symptoms without increasing the unit dose of protamine-insulin or taking regular insulin. Two patients had symptoms of hypoglycemia following the first evening injection of protamine-insulin. With one patient the symptoms began about 4 a. m., several hours before the injection of regular insulin was due. The second patient experienced hypoglycemic symptoms two hours after breakfast. These were evidently influenced by the morning dose of regular insulin. These symptoms continued more or less severe until about 9 p. m. even with extra carbohydrate taken during the day to at least 80 grams.

* * *

Eight patients were never able to come under satisfactory control with plain protamine-insulin during several weeks of close observation. Blood sugars were maintained at a more even level, but held values of 200 to 300 milligrams, with high percentage of glycosuria. Since protamine-insulin in combination with either zinc or calcium has been available, these patients have responded with more satisfactory control. The studies of Scott and Fisher[7] on the effects of giving diabetic dogs protamine-insulin combined with small amounts of zinc, and the experimental and clinical studies reported by Kerr[8] indicate a longer insulin effect with zinc than was found with protamine-insulin alone. During the short time that the Lilly preparations, that combine either zinc or calcium with protamine-insulin, have been available, there has been an increasing amount of evidence that these combinations give insulin effects of longer duration than has been found with plain protamine-insulin solutions, with less diabetic disturbance at the beginning of the treatment or with any change either in unit dosage or in time of injection. Which of the two preparations, zinc or calcium, is the more stable and will give the longer insulin yield is now being studied. The blood sugar curve of Table 2 gives evidence of the degree of diabetic control possible with calcium protamine-insulin.

* * *

But two patients of the twenty-five here reported have continued to take regular insulin for one period of the day. One takes this for the morning insulin and the other for the late night dose. Several patients of this group studied had to change back to the regular insulin for several days. This shift was made without disturbance, and the later change back to protamine-insulin caused none of the evidence of loss of diabetic control that appeared earlier.

IN CONCLUSION

1. Those diabetic patients who have used regular insulin for some time before beginning protamine-insulin often show an acute diabetic disturbance that may last from three to five days. Loss of control to some degree may immediately follow any slight change in unit dose, or in time of protamine-insulin injection. Failure to secure satisfactory control with the new insulin may result from frequent changes in time of injection or in unit dose.

2. In the group of patients now reported, it was found that the protamine-insulin had a unit value somewhat less than U-40. Usually four to eight units more were required with the protamine-insulin solution. Since the zinc and the calcium combinations have been used there is evidence that these are more nearly the same in unit value as regular insulin of U-40 strength.

3. Observations indicate that an interval between protamine-insulin injections of twelve hours gives satisfactory results, rather than giving the dose in relation to meals.

4. Change from protamine-insulin to regular insulin and back again to the protamine can be done without serious disturbance in control.

5. All patients have expressed a feeling of increased endurance and relief of periodic fatigue soon after beginning protamine-insulin, even before satisfactory control is obtained.

6. Hypoglycemia may be difficult to correct because of the continued absorption of insulin, and may appear at the beginning of the change to protamine-insulin, when regular insulin is taken at one or more periods. Subnormal values for blood sugar may be found without definite symptoms. This may require more frequent blood sugar tests, especially in patients with some cardiovascular complication. The more even blood sugar control should give greater safety for these patients in that there should not be the rapid drop in blood sugar that was occasionally found with regular insulin.

7. Patients using protamine-insulin should be warned of the necessity of keeping the preparation in the icebox after mixing, and to shake the bottle before each withdrawal of dose.

8. The combinations of insulin with protamine buffer, together with either zinc or calcium, give a more even blood sugar control throughout the full twenty-four hours than has been possible with regular insulin alone in the severe diabetic. Clinical observations for longer time will give the full picture of value for these new preparations, but the controls secured in the months they have been used offer great hope for the future.

Discussion *by H. Glenn Bell, M.D., San Francisco: Mark Lewis Emerson, M.D., Oakland; Harold Brunn, M.D., San Francisco; John B. deC. M. Saunders, F.R.C.S., San Francisco.*

CARCINOMA involving the splenic and hepatic flexures has too frequently been regarded as inoperable because of the difficulties of resection and the high mortality occasioned by the removal of this portion of the bowel. For this reason many palliative operations have been done. Permanent colostomies are necessary at times, but they have many objectionable features, and should be avoided if reëstablishment of the continuity of the bowel is at all possible without too great a risk.

DIFFICULTIES AND DANGERS OF RESECTION

The difficulties and dangers of resection have been caused largely by the poor exposure through the usual anterior route, making the operation long and subjecting the patient to shock; in addition, the flexures are fixed and inaccessible, the blood supply comes from the posterior wall still farther from the incision, and it is often impossible to remove completely the glandular metastases in the surrounding tissues. If the patient survive the immediate operation, too frequently he is left with a permanent colostomy or fistula, and eventually dies of infection or a recurrence of the disease.

Some of our surgeons argue that a permanent colostomy can be made so inoffensive that it is not objectionable. It is always, however, a source of great care, gives an unmistakable odor however perfectly it may function, and leaves the patient with a physical handicap and mental distress.

We do not hesitate to resect a cancer of the stomach even in the presence of known metastases in the liver, and in spite of a fairly high mortality rate, because, without resection, patients with this lesion lead a miserable existence; on the other hand, if resection is successful they may live fairly comfortably for from one to five years. In my opinion we should adopt a similar attitude toward cancer of the colon.

The transverse incisions through the rectus muscle or the combined rectus and costal incisions have never become popular as a method of opening the abdomen, because of the time consumed in closure and because the wall is weakened in a high percentage of cases due to interference with the nerve supply, or infection. The lumbar incision of Koster,[4] "extending from the tip of the twelfth rib to the anterior-superior spine," approaches the mesenteric vessels from the retroperitoneal space, and gives a fairly good approach to the blood supply but does not give adequate exposure for a rapid and complete excision.

INCISION USED BY THE AUTHOR

I have been using a pericostal-transabdominal incision which parallels the twelfth rib and extends from the lumbar fascia in the back to the sheath of the rectus abdominis muscle in front, at the level of the umbilicus—a modification of the usual incision for exposure of the kidney. Instead of curving downward toward the groin, the incision curves upward around the tip of the twelfth rib, extends to and nicks the sheath of the rectus muscle, but does not transect the muscle itself. If it interferes with the innervation of the musculature at all it is only to a slight degree.

It would seem that this incision should violate every principle of good surgery by dividing both muscle fibers and their nerve supply, which would make herniation inevitable. This, however, is not the case. The recent work of Coyte,[1] and Davies, Gladstone and Stibbe,[2] has shown that the eleventh intercostal nerve does not course directly across the abdomen, as our anatomies have taught us, but first loops downward before entering the rectus muscle just above the umbilicus, and then again turns downward within its fibers. The lower dorsal nerve (subcostal or twelfth nerve) does not follow the twelfth rib, but comes out much lower and nearer the spine, with the ilioinguinal and iliohypogastric nerves, and after looping downward, enters the rectus muscle below the umbilicus and courses downward. This incision is made between and parallel to the eleventh and twelfth nerves, which explains the lack of injury to the nerves and lack of degeneration of the muscles which we have found in actual practice. It may be of interest that this incision was developed and used successfully before the true anatomic arrangement—which explains its anatomic soundness—was suspected.

Formerly we were taught that each segment of the rectus muscle was innervated by a single nerve, and that severance of that nerve would result in atrophy of the corresponding segment. In actual practice, however, this complication was seldom seen. An explanation of this fact is offered in the work of Davies, Gladstone and Stibbe,[2] who stated, in a recent article: "Moreover, any one nerve at the lateral border of the rectus is distributed to two segments of muscle. It is certain, therefore, that the rectus segments do not receive a segmental nerve supply, but that each segment is supplied by three segmental nerves at least." Goinard[3] also suggested that the nerve fibers actually cross the linea alba of the rectus muscle. So far this lacks proof.

TECHNIQUE OF OPERATION

A table with a kidney lift is necessary for this procedure. The patient is placed on his sound side with the leg on that side extended, the other leg flexed, the body tilted slightly backward and the back supported on sand bags. This position is the reverse of that used for exposure of the kidney. The skin incision extends from the juncture of the twelfth rib with the spine, to the outer border of the rectus muscle at the umbilicus. The external and internal oblique and transversalis muscles are divided without regard for the direction of their fibers. The anterior portion of the latissimus dorsi muscle is transected and the lumbar fascia divided. Anteriorly, the incision extends into the fascia of the rectus muscle, and the anterior and posterior leaves are partially divided. The nerve supply entering the rectus muscle is readily seen and avoided. The peritoneum is opened widely and the kidney lift is elevated. This, the elevation of the kidney lift, is the most important single step of the operation, for it is the means by which adequate exposure is secured. It more than doubles the normal distance between the twelfth rib and the iliac crest by opening the incision like the spreading of a mouth, and at the same time it tilts the costal margin upward, bringing the colon with its flexure into view. The intestines fall away and seldom show any tendency to bulge out of the wound, so that packs are required only for walling off the intestinal cavity. The space is, in fact, so wide that a Balfour retractor spread to its greatest extent will not remain in position.

On the right side this incision allows ready access to the cecum, ascending colon, hepatic flexure and the right half of the transverse colon. On the left side it exposes the descending colon, splenic flexure and the left half of the transverse colon. It permits a fair exposure of the spleen.

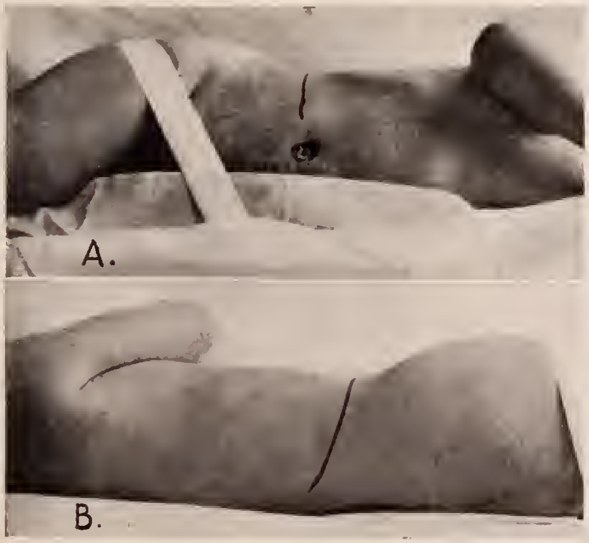

Fig. 1.—Position of patient on table, back supported by sand bags. Line of incision. (Kidney lift is raised *after* incision is made.)

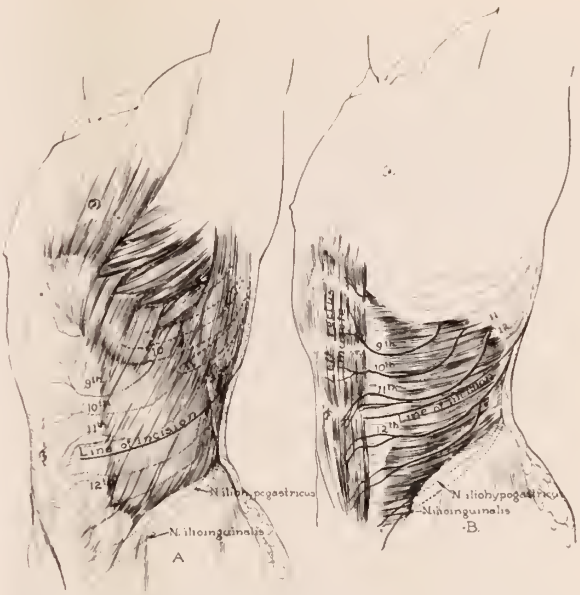

Fig. 2.—Course and distribution of the abdominal nerves. Line of pericostal-transabdominal incision between eleventh and twelfth nerves.

According to Ewing's statistics of 297 cases of carcinoma of the colon, exclusive of lesions of the rectum, the following disposition was found: cecum, 47; ascending colon, 22; hepatic flexure, 19; transverse colon, 44; splenic flexure, 31; descending colon, 10; sigmoid colon, 124. Of these, at least 129, or 43 per cent, could best be approached through the incision described.

The great majority of malignant lesions of the colon are not diagnosed as such, nor are they localized until obstruction occurs. Once the lesion is localized our procedure has become pretty well standardized.

A two-stage operation has been found to reduce the mortality greatly, first, by relieving the obstruction, if present; secondly, by allowing for improved nutrition; thirdly, by vaccinating the patient so that the reaction to infection in the second stage of the operation is minimized; and fourthly, by reducing the magnitude of any one single operative procedure. The possible exception to the two-stage operation is the Mikulicz technique which, when indicated, may be done in either one or two stages.

RESECTION OF THE LESION

The first stage, done commonly through a rectus or McBurney incision, has a two-fold purpose. First, an exploration to determine the position and extent of fixation of the lesion, and whether or not metastases are present; and, secondly, a decompression of the bowel, either by a sidetracking anastomosis or by some type of colostomy. On the right side an anastomosis (usually side to side) of the lower ileum to the transverse colon is the procedure of choice, with or without transection of the distal ileum. On the left side, the situation is more complicated. If the lesion is near the splenic flexure it is a temptation to sidetrack the contents of the bowel by an anastomosis of the transverse colon to the descending colon,

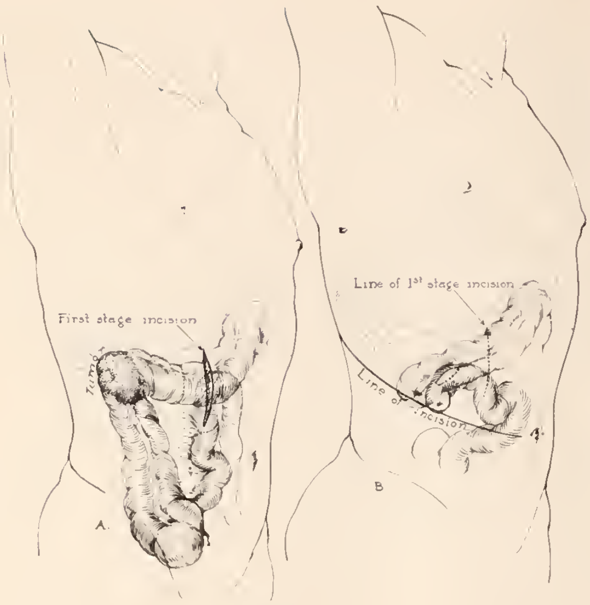

Fig. 3

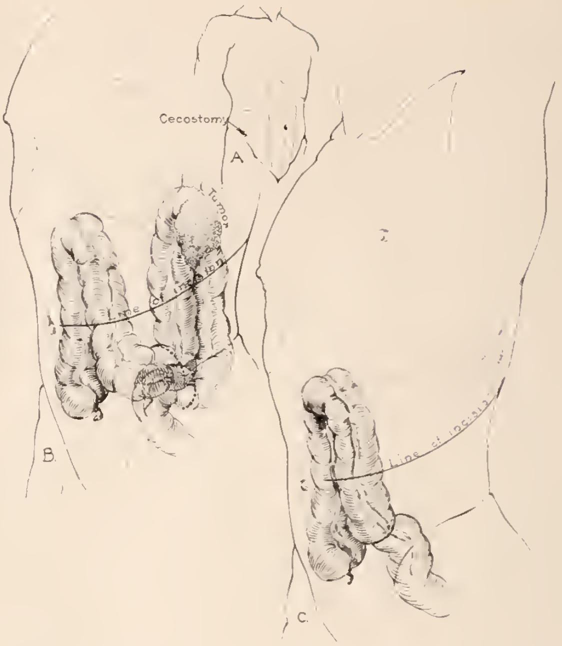

Fig. 4

Fig. 3.—Schematic drawing of procedure for lesions of the right side. (*a*) First stage operation through right rectus incision with an ileo-transverse colostomy. (*b*) Second stage pericostal-transabdominal incision with resection of terminal ileum, cecum, ascending colon and first portion of transverse colon.

Fig. 4.—Schematic drawing of lesions of left side. (*a*) First stage. High McBurney cecostomy (or colostomy if preferred). (*b* and *c*) Choice of these two procedures is optional. (*b*) Pericostal-transabdominal incision, lateral anastomosis with or without resection of tumor. (*c*) Pericostal-transabdomianl incision with resection of tumor and end-to-end anastomosis.

or sigmoid. Too many complications, however, arise from any primary anastomosis to the descending colon or sigmoid, and the mortality rate from this procedure ranges from 25 to 50 per cent. A preliminary cecostomy or colostomy proximal to the lesion makes such an anastomosis much safer, by decompressing the bowel and vaccinating the patient against infection. A cecostomy is more readily closed whenever it becomes necessary to reëstablish the continuity of the bowel, but it seldom diverts the intestinal stream satisfactorily unless obstruction is present. If there is no obstruction a colostomy is preferable.

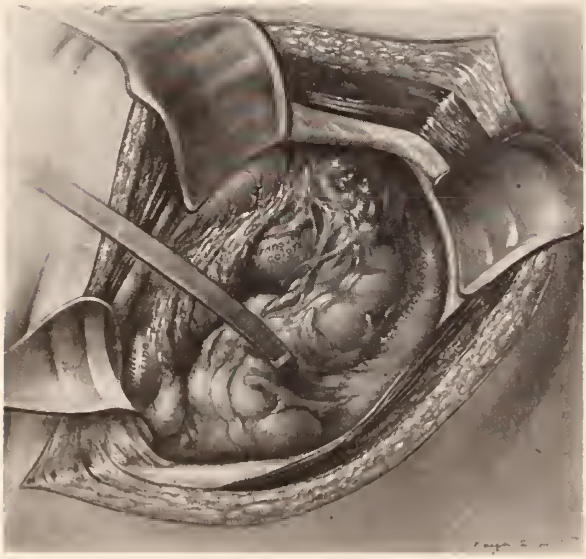

Fig. 5.—Left pericostal-transabdominal incision spread open by elevation of kidney lift showing splenic flexure, descending colon, with line of incision in mesentery.

Some writers advocate a so-called "blind" cecostomy when obstruction is present. The operation is done through a high McBurney incision under local anesthesia, and without any attempt at exploration. While this may be the procedure of choice in certain depleted patients, it leaves the operator in doubt as to the nature and magnitude of the subsequent operation. There is usually no contraindication to exploration of the abdomen in chronic obstruction, even though it requires general anesthesia, and frequently it can be done satisfactorily through the McBurney incision, which is to be used for the cecostomy.

In the second stage, the abdomen is opened through the pericostal-transabdominal incision described above, and the intestines are packed off. The posterior layer of the peritoneum along the mesentery is divided and the ureter located. If the lesion is on the right side the ileo-colic branches to the terminal ileum and the right colic artery are clamped and ligated, and the mesentery with its vessels is divided so that the bowel is released. The suspensory ligament (hepatico-colic) is severed and with this the entire flexure falls downward and can be lifted out of the wound. Care must be taken not to injure the right kidney or duodenum when the mesentery is divided. If a previous ileo-transverse colostomy has been done the entire cecum, ascending colon and a portion of the transverse colon, with any metastases present, are then removed and the end of the gut is closed in the usual manner.

On the left side the second stage procedure is similar. After opening the abdomen through a pericostal-transabdominal incision, the peritoneum is opened along the descending colon, the left colic artery is ligated and the mesentery is divided. Involved lymph glands are removed with the mesentery. The phreno-colic ligament is cut, liberating the flexure. Injury to the spleen, pancreas, stomach and kidney must be avoided. A lateral anastomosis between the transverse colon and the descending colon or sigmoid may be done, followed by removal of the lesion and closure of the ends of the gut; or preferably the lesion may be released and removed, and an end-to-end anastomosis done. In my experience the end-to-end anastomosis is a shorter and more satisfactory procedure. It can be done by the usual open method, but the use of the Furniss clamp and pin has proved to be more rapid, aseptic and generally more satisfactory than any method which I have used up to this time. In any end-to-end anastomosis it is important to note carefully whether or not the blood supply to the remaining stump is adequate before selecting the site for transecting the bowel, and the longitudinal bands should be approximated as far as possible. Any disproportion in the diameter of the two segments of gut to be anastomosed is overcome by slanting the line of transection of the smaller one. I have used interrupted black silk mattress sutures for the inner layer of this anastomosis, with a running catgut suture covering it, or interrupted black silk throughout. The large bowel tolerates silk very well, and little difficulty may be expected if an interrupted type of suture is used. The opening in the mesentery is either closed tightly to prevent herniation of the intestine, or if it does not come together well it should be left wide open and no attempt made to close it.

CLOSURE OF THE INCISION

The kidney lift is lowered, allowing the edges of the incision to fall together. The peritoneum is closed with a continuous suture, and each muscular layer is brought together with interrupted mattress sutures, everting the edges. In some of my patients closure has been made with silk, but catgut has been used in the more infected. For those who have shown the greatest amount of infection or inadequate hemostasis of the vessels in the muscle, drainage for forty-eight hours has been instituted by means of a rubber-dam wick inserted down to the peritoneum, or between the muscular layers, and brought out through the posterior angle of the incision for dependent drainage. This places the opening for drainage over the erector spinae muscles.

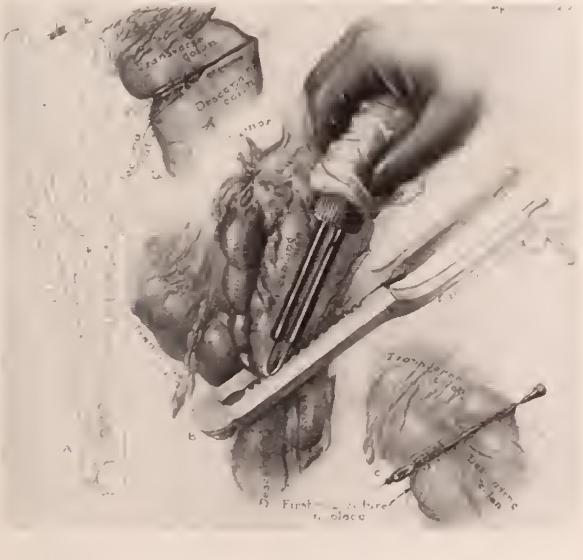

Fig. 6.—(*a*) Furniss clamp showing seration in teeth for passage of pin. (*b*) Application of Furniss clamp to both loops of splenic flexure. (The pin must be inserted before the loop is removed with the cautery.) (*c*) Both loops of gut held by pin with guard and first row of sutures. (*d*) A second row is supplied. The anastomosis is then rotated 180 degrees and the same suturing technique completed before the pin is withdrawn.

B

Fib. 7.—Closure of peritoneum with continuous sutures; closure of muscle layers with interrupted everting sutures. External and internal oblique and latissimus dorsi transected, transversalis split, rectus abdominis muscle fibers exposed.

Once the incision is closed there is little strain upon it, as distension of the abdomen tends to pull the edges of the muscle together rather than to separate them. This in itself is an important factor in preventing herniation.

REPORT OF CASES

Two typical cases selected from a series of ten.

Case 1.—Mrs. M. P. B., aged 46 years, was seen first on June 15, 1934. For at least two months the patient had had indefinite pains in the abdomen, with considerable rumbling and evidence of an incomplete obstruction. Roentgen examinations of the gastro-intestinal tract had been made, but no obstruction was noted. While in another city the patient had so much pain that additional x-ray examinations were made, but, again, no definite point of obstruction was found. On her return to San Francisco, obstruction was nearly complete, a barium enema failed to pass beyond the hepatic flexure, and gas-filled bowel could be seen proximal to this point.

Exploration was done through a right rectus incision on June 16, 1934. Little could be seen in the abdomen except dilated small bowel and ascending colon. Palpation of the hepatic flexure showed a small annular constriction. The mass, apparently a carcinoma, was very small, and certainly would have been overlooked in any exploratory operation had not the point of obstruction been known. A lateral anastomosis was made between the terminal ileum, some fourteen inches from the cecum, and the transverse colon. The patient made an uneventful recovery, and normal bowel habit was reëstablished. The lesion was so far from the incision made for the exploration that it seemed quite impossible to remove it through any type of right rectus incision.

Four weeks later a pericostal-transabdominal incision was made. The kidney lift was elevated, and the entire ascending colon and flexure could be seen and palpated. The ilio-colic and right colic vessels were identified and ligated, and the entire cecum, ascending colon and one-third of the transverse colon were liberated. One metastatic gland was found in the mesentery and removed with it. The bowel was divided with the cautery proximal to the original anastomosis, and removed. The ends were closed with inversion sutures. The patient's recovery was uneventful; there was no interruption of bowel habit and there was little shock connected with the operation. The pathological diagnosis was adenocarcinoma.

* * *

Case 2.—Mrs. F. B., aged 38 years, was seen first on August 16, 1935. The patient had had symptoms of a partial obstruction for a number of months, and had had an appendectomy without relief. As time went on she developed an obstruction, and exploration revealed a lesion at the splenic flexure. A transverse colostomy was done on the right side. Three weeks later, her condition having improved, the abdomen was opened through a left pericostal-transabdominal incision. A rather large lesion, completely surrounding the bowel and with some metastases in the mesentery, was found. Beginning distal to the lesion the mesentery, with the involved glands, was dissected free and the entire mass released. The transverse colon was then approximated to the descending colon with the longitudinal bands in approximation, the loop was crushed with the Furniss clamp and fixed with the pin, and the lesion was removed with a cautery. An end-to-end anastomosis was done over the pin with an inner layer of mattress silk sutures and an outer layer of gastro-intestinal catgut. The peritoneum was then closed and, because of possible soiling, a rubber-dam drain was inserted down to the peritoneum. The wound healed very well, but there was a considerable amount of infection and drainage. In spite of this, the wall became firm. Three weeks later the colostomy was deepened and closed. At this time a finger was inserted through the drainage channel of the pericostal-transabdominal incision and it was found to lead into muscle, and to be surrounded by very firm wall.

Recovery was uneventful and a barium enema on March 6, 1936, showed no evidence of recurrence of the lesion and no indication of the point at which the anastomosis had been made. The pathological diagnosis was adenocarcinoma.

The other eight cases operated by this technique are so similar that they are not reported in detail.

SUMMARY

1. A new method of operative approach by a pericostal-transabdominal incision parallel to the actual nerve supply gives an excellent exposure of the colon and its flexures, and permits their more rapid and complete removal.

2. The use of this incision permits resection and reëstablishment of continuity of the bowel rather than a permanent colostomy for a greater number of patients. It is hoped that the procedure will be a potent factor in reducing the morbidity and mortality of certain lesions of the colon.

3. Recent investigations of the innervation of the abdominal and rectus muscles have shown it to be different from that long accepted by our older anatomists.

DISCUSSION

H. Glenn Bell, M. D. (University of California Hospital, San Francisco).—Doctor Hoag has devised a very interesting approach to the flexures of the large bowel. We have used it at the University of California Clinic on several occasions and find that we get a thoroughly adequate exposure—one which is superior to that afforded by either a right or a left rectus incision. It permits us to protect the edges of the wound so that, even if we do an open anastomosis of the large bowel, we may anticipate having the wound heal per primum. This has been the result on several occasions.

It is always interesting to have someone refresh our memories as to the anatomical structures of the abdominal wall, particularly the nerve supply. The making of the incision described requires, perhaps, a little more time than the usual type of incision—particularly if one is careful to obtain adequate hemostasis. The time spent in opening the abdomen, however, is more than justified by the ease with which the required surgical procedure can be accomplished. Through this approach we have been able to resect the tumor and do an end-to-end anastomosis. We do not, of course, do this in one stage. In each instance we have done at least a cecostomy many days before.

Doctor Hoag is to be commended for bringing before us this incision for use in selected cases.

*

Mark Lewis Emerson, M. D. (1624 Franklin Street, Oakland).—In discussing the incision which has been so ably presented to you today, allow me to refer you to Gray's Anatomy, which shows a plate of the inner surface of the posterior abdominal wall after the colon has been removed. You will then see how deep and how close to the spine the two flexures of the transverse colon are situated. It is the surgical approach to this difficult position that is so greatly facilitated by the incision devised by Doctor Hoag. Lesions in either flexures of the colon are not amenable to enucleation and any attempt at the same, especially in the presence of inflammation or extensive pathology will favor operative perforation of the bowel, the most common cause of peritonitis in this type of surgery.

The mesenteric attachments of the colonic flexures must be cut around, either by knife or scissors, including the posterior peritoneum, before mobilization and delivery of the tumor can be accomplished.

The incision advocated by Doctor Hoag not only facilitates this dissection, but also gives a quick approach to various organs in the upper quadrant of the abdomen such as emergency wounds of the spleen, kidney and bowel. Some operators are making the incisions too low, others are attempting to include the author's incision as a lateral extension from the vertical rectus incision whenever the latter is inadequate. Doctor Hoag takes advantage of the decreased shock resulting from the use of a table lift to spread the incision, but he has no objection to retention retractors when the operator deems it necessary. The wide field given by this incision is often all that is necessary to make a lateral posterial approach to the upper angulations of the large bowel.

Doctor Hoag has been working many months on this incision, giving his time to instruct other operators how to use it, and all operators that I have seen use this incision have been most enthusiastic because of benefits derived.

I congratulate Doctor Hoag on his perseverance and his patience in so thoroughly trying out this work before presenting it to you today, also allowing the judgment of others to assist him in his final conclusions.

*

Harold Brunn, M. D. (384 Post Street, San Francisco).—Doctor Hoag is to be congratulated on developing a new incision which gives a great deal of room and easy working space in the upper abdomen on either the right or left side. There has been a tendency toward transverse abdominal incisions for some time. This type of incision seems to have the habit of becoming popularized and then disappearing from view and being rediscovered.

The incision of Doctor Hoag's, however, is somewhat different and does give access to a region which is very difficult to reach with the ordinary longitudinal incision through the right rectus.

It is not unusual in abdominal operations, when an exploration has been made through the right rectus, to find it necessary to make a transverse incision either to the left or right in order to obtain more room. Doctor Hoag, however, has developed this operation to its greatest extent and shows how, if properly made and extensive enough in the back, a longitudinal incision is not necessary. I am sure that this method of approach should always be considered when any mass is to be removed either from the right or from the left side, especially those that may be retroperitoneal or for large tumors involving either kidney.

The pictures which illustrate the article are exceedingly good and should be carefully studied in order that the incision developed by Doctor Hoag should be used as described.

*

John B. deC. M. Saunders, F. R. C. S. (University of California Medical School, San Francisco).—The approach devised by Dr. Carl Hoag for resection of cancers involving the colonic flexures is a distinct and valuable contribution to surgery. There can be little question that an approach of this type is, in view of its directness, the most logical procedure for exposure of the flexures, which structures are deeply placed in the flanks; in the wide hollows on either side of the prominent bodies of the lumbar vertebrae. The problem raised by such an approach is the question as to whether or not the essential nerve supply of the musculature can be preserved in order to maintain the integrity of the abdominal parieties. Our conception of the course and distribution of the intercostal nerves has undergone considerable changes from those which are to be found in the standard textbooks of anatomy. Doctor Hoag has mentioned the recent work of Davis, Gladstone and Stibbe on the intercostal nerves, which merits the close attention of all those who are interested in problems of abdominal approach. We have been able to confirm for the most part the findings of these authors, findings which indicate that this route is anatomically sound. There can be little question that an approach of this type secures the most adequate exposure of the colon that it is possible to obtain. The position of the patient is an additional advantage in that the abdominal contents are carried out of the way and do not obstruct the field.

The dictum that the surgery of carcinoma of the large bowel is dependent upon its lymph drainage and vascular supply has now become axiomatic. An approach which enables us to reach with ease the vessels of the colon, to mobilize the bowel and to perform wide resection of the lymph bearing area is a decided advantage. The value of this route is nowhere better illustrated than in cases of carcinoma of the splenic flexures. It is well known that recurrences after resection of this flexure invariably occur in the region of the hilum of the spleen. The usual anterior type of approach renders it difficult to deal with this area, whereas by means of the postero-lateral route described by Doctor Hoag this region is readily accessible.

Doctor Hoag is to be congratulated on the approach which he has devised as it presents so many valuable features in dealing with malignant disease affecting the colon. Exposures of this type warrant a more extensive use than has been accorded to them in the past.

ADRENAL ENDOCRINOPATHIES IN CHILDHOOD*

By H. Clare Shepardson, M.D.
San Francisco

Discussion *by Rieta C. Hough, M.D., San Diego; Frank Hinman, M.D., San Francisco; Francis Scott Smyth, M.D., San Francisco.*

Although Eustachius discovered the adrenal glands in 1563, their importance was not suspected until nearly three hundred years later when Addison, in 1855, showed their relation to the disease known by his name. In the human there are two adrenal glands, which lie embedded in the fat above the kidney on either side. These small triangular or cocked-hat shaped bodies are composed of two parts, cortex and medulla, which, although anatomically united, are morphologically and embryologically distinct structures. The cortex is derived from the mesothelium of the Wolffian ridge, as are also the ovary and testis, while the medulla takes its origin from the intraneural ectoderm that gives rise to the nerve cells of the sympathetic ganglia. In the higher animals the anatomical contiguity of these derivations of the interrenal and chromaffin systems is so intimate that they are fused into a united gland. However, accessory adrenals or aberrant masses of adrenal tissue are met with frequently. These are often quite small, and are found usually in one of four chief locations, in the kidney along the suprarenal vein, near the solar plexus and the inferior surface of the liver, about the uterus, ovary and tube, and in the spermatic cord and corpus Highmori.

ADRENAL GLANDS A FAVORITE FIELD OF STUDY FOR THE EXPERIMENTAL PHYSIOLOGISTS

Of all the members of the ductless glandular apparatus, the adrenals have been the happy hunting grounds de luxe for the experimental physiologist. Yet, despite the amazing ingenuity of these indefatigable workers, the present state of our knowledge regarding the physiology of the adrenal is still far from satisfactory. Extirpation of one adrenal has little or no apparent effect, although when both are removed death speedily ensues. While much controversy has surrounded the question as to which portion of the adrenal body is essential to life, it has now been demonstrated that death is due to removal or destruction of the cortical substance and not to loss of the medulla. Unfortunately, "up to the present time it has not been possible to produce experimentally any well characterized symptoms associated with adrenal insufficiency. The operator either leaves so much of the gland that the animal survives indefinitely in good health, or takes away so much that it dies quickly, as it would have done if the glands had been totally excised." (Stewart.) No intermediate state between health and death has been achieved. As a result many details of the physiology of the adrenals are still unknown or contradictory. However, with the isolation of an active cortical hormone (or hormones) by Hartman, and by Swingle and Pfiffner, a new chapter in the physiology of these glands, particularly the "indispensable to life" portion, is being written.

ADRENAL GLAND FUNCTION FREQUENTLY MISINTERPRETED

Heretofore, all manner of conditions have been ascribed to disturbance in function of the adrenal glands, particularly insufficient activity, mostly as a result of a slightly lowered systolic blood-pressure. It is a simple matter to fasten the label of adrenal deficiency on to any individual who feels somewhat below par, and whose blood-pressure ranges between 100 and 110 millimeters of mercury. Thus we have seen the hypoadrenal constitution, the hypothetical hypoadrenalism associated with infectious diseases, and various and sundry intoxications and dyspepsias. It has been inferred that many or all of these so-called hypoadrenal states are mild, incomplete forms of Addison's disease, and this in spite of the fact that experimental physiology affords no basis for the view that loss of the epinephrin secretion of the medulla is in itself important. Stewart has shown that arterial hypotension is not caused even when the epinephrin output is totally suppressed.

No mention will be made of the multitude of conditions at one time or another ascribed to adrenal disturbance, when the evidence for such relationship is either faulty, dubious or purely imaginative. There are, however, a few clinical syndromes in which adrenal lesions of unimpeachable character have been repeatedly discovered. And even in these maladies, where the adrenal pathology is beyond question, the functional interpretation of the clinical manifestation is often difficult, doubtful or impossible.

ANOMALIES OF THE ADRENAL BODIES

Anomalies of the adrenal bodies have little clinical significance. Usually they are found associated with cerebral defects. Zander discovered abnormally small adrenals in forty-two cases of hemicephaly. Hypoplasia of the adrenal cortex has accompanied anencephalus and may be associated with pituitary anomalies. In Czerny's five cases of congenital hydrocephalus, the medullary portion of the adrenals was entirely lacking. In Elliott and Armour's case of anencephaly the adrenal cortex was absent. These congenital malformations are extremely unusual, and so bizarre that it is impossible at present to determine whether the cerebral and adrenal anomalies are merely coincidental, or whether the brain abnormalities are in some peculiar way dependent on the adrenal defects.

ACUTE ADRENAL INSUFFICIENCY

Acute adrenal insufficiency, with symptoms quite different from those of Addison's disease, occurs in the so-called suprarenal apoplexy of small children. Virchow first called attention to the condition. The characteristic symptoms are sudden onset with fever, violent pain in the hypochondrium radiating to the loin, later tympanites, collapse and death within forty-eight hours of the onset of the attack. Glauzmanns' review, in 1933, refers to this condition, which in small children is frequently accompanied by cutaneous purpura, as the Waterhouse-Friderichsen syndrome. As Osler pointed out years ago, the picture presented by acute hemorrhagic adrenalitis resembles quite closely that of acute pancreatitis. However, the degree of shock in the former is more profound than that encountered in acute pancreatitis, or in peritonitis or ileus.[2] The destructive hemorrhage may occur in adrenals that were previously healthy, or in those that were the seat of disease with or without symptoms. In the searching for etiological factors responsible for this condition, a great number of theories have been advanced. Kempf[3] calls attention to the developmental changes taking place in the adrenals, both in intrauterine life and particularly in the first twelve months after birth. From the first month to the twelfth month postpartum, there occurs a capillary hyperemia of the inner layer of the adrenals which at birth consists mostly of cortex, except for small complexes of medullary cells dispersed about the veins. After the second month this hyperemia is marked and there occurs fatty, vacuolar and colloid degenerative changes in the cortical cells, the atrophic cells being replaced by the medullary cells which ever increase in number as if being able to withstand the pressure of the hyperemia to which the cortical cells succumb. It is this hyperemia and destruction which Kempf claims is the most important predisposing factor in adrenal hemorrhage in the young.

Many clinicians have assigned the dominant rôle in the production of symptoms to variations in the epinephrin output. It is the general impression that a marked diminution of epinephrin is of serious import, its total suppression a calamity. However, like many other clinical impressions, these are not supported by experimental data; for, as has been mentioned, there is no evidence to show that diminution in the ordinary rate of output of epinephrin can give rise to symptoms. Yet it can only with difficulty be presumed that the lethal outcome results from destruction of the cortex, for fatal cases have been reported in which the cortex was morphologically well preserved.

Diagnosis during life is very difficult. The presence of severe abdominal symptoms with few or no physical manifestations, profound asthenia and gradual decline of blood pressure should suggest the presence of acute hemorrhagic adrenalitis. The leukocyte count is apt to be high and there may be a marked hyperpyrexia.

Treatment of bilateral suprarenal apoplexy has met with little success. Surgery offers no help.[2] The administration of large amounts of sodium chlorid, together with cortical extract, sedatives and even adrenalin, seem only to postpone the fatal outcome.

CHRONIC ADRENAL INSUFFICIENCY

Chronic adrenal insufficiency, first described by Thomas Addison, in 1855, results in a symptom complex universally associated with the name of its discoverer. While Addison's disease is preponderantly one of the fourth, fifth and sixth decades, it may occur at any age. Osler described a congenital case in which the child lived eight weeks. The youngest patient in Rowntree's[4] series of approximately three hundred cases was fourteen years of age. Morabito,[5] in his article on Addison's disease in infancy, remarks that the disease is rare in infancy, probably because the suprarenal glands possess special resistance to tuberculous infection and to other processes that lead to this disease.

It is generally accepted that in spite of the fact that the condition has not been produced experimentally, a hyposecretion of both the medulla and the cortex of the adrenal glands is the causal factor of the disease (although the recent suggestion by Wilder [6] that Addison's disease may have to be considered as resulting from disturbed function of the anterior hypophysis, as well as the adrenals, may prove extremely important). While any pathologic lesion which destroys the suprarenal bodies will produce the characteristic syndrome in whole or in part, tuberculosis is, of course, the commonest cause. It is interesting, however, that only one third of Rowntree's patients had clinical evidence of tuberculosis and that Addison's disease is extremely uncommon in patients in sanitariums. In Lewin's[7] series of five hundred cases, tuberculosis was present in about one-third. It should be added that atrophy or hypoplasia of the adrenals is a more common cause of this disease than has heretofore been supposed, although such pathologic changes are only rarely encountered in childhood.

The disease is characterized clinically by marked asthenia, resulting from both muscular and vascular weakness, continued and extremely low blood-pressure, a characteristic brown or chocolate colored pigmentation of the skin and mucous membranes, especially of the mouth, gastrointestinal symptoms including diarrhea, vomiting, pain in the epigastrium and later complete anorexia, and loss of memory, delirium, dizziness, tinnitus and other nervous and mental manifestations, such as constant apathy, depression, insomnia or rarely, increased tendency to sleep. The temperature is usually subnormal; there is no anemia except that resulting from such complicating diseases as tuberculosis or cancer. The blood sugar is low. Other laboratory procedures give little aid in diagnosis; although ordinarily little trouble is experienced, for the picture is one which can scarcely be confused with any other clinical syndrome.

Until quite recently the treatment of Addison's disease has been rather a thankless task. Even now the course of the disease usually is progressively downward, although occasionally a patient seems to recover spontaneously; remissions may occur, persisting for a number of weeks, months or even years. Until three or four years ago progress toward remedy of this malady was negligible in spite of the heroic efforts made to administer the only active extract of the adrenals then known, epinephrin, orally, rectally and by hypodermic. No convincing improvement ensued from medullary adrenal therapy. More recently, however, improvement seemingly has followed the administration of the adrenal cortical extracts of Swingle and Pfiffner, and of Hartman. It is as yet premature to forecast the ultimate scope of adrenal cortex therapy in Addison's disease, but it is obvious that the isolation of this hormone constitutes one of the major advances in endocrinology. Lisser, Taylor and Leet,[8] in summarizing the accomplishments of cortical extracts in the treatment of Addison's disease, state that while enough persons who would have succumbed almost certainly within twenty-four hours have been revived by cortical extracts, to banish any doubt as to the specificity or potency of this hormone, further purification and concentration are needed. The expense involved in administering adequate doses is prohibitive except in isolated instances. Cheaper methods of extraction are most desirable, so that these preparations can receive the clinical application they deserve. During crisis, daily injections of 50 to 100 cubic centimeters of this hormone, as it now exists, are required. This tremendous dosage may be necessary for several days, although subsequently the patients' health may be maintained with as little as 2 cubic centimeters daily. In most instances, however, the maintenance dose varies from 3 to 5 cubic centimeters daily. Consequently, the actual use of this hormone has been restricted to the very few who can afford it, or to such clinics as are richly endowed.

It is altogether probable that the suggestion made by Harrap that a high salt intake may markedly reduce the need of cortical extract, except in times of crises, will aid in solving to a certain extent the problem of costliness. Sodium chlorid should be given daily in doses of 1 to 7 grams.

Finally, it should be added that once the hormonal deficiency is adequately replaced, the problem of the chronicity and of the tuberculosis must still be faced.

MEDULLARY TUMORS

Inasmuch as the anlage of the suprarenal medulla lies in the sympathetic ganglions, which in turn are derived from the neural crest, medullary growths are of neuroblastic origin. Two forms are usually encountered: the type described by Hutchinson and the one depicted by William Pepper (III). They usually occur during infancy or early childhood.

The Hutchinson variety is characterized by metastatic involvement of the orbit, skull and long bones. Ecchymosis of one or both eyelids, soon followed by exophthalmos, is a frequent occurrence. The discoverer of this peculiar syndrome originally reported thirteen cases in children from three months to nine years of age.

The Pepper type is characterized by its rapid growth and its tendency to metastasize to the liver, lungs or abdominal lymph-nodes. The liver especially may be diffusely involved, the abdomen becoming greatly distended, but without ascites or jaundice.

In a third and very rare clinical type of neuroblastoma, the symptoms of severe secondary anemia develop. The case may be mistaken for one of pernicious anemia.

Mention is made of these three types of medullary tumors simply for the sake of completeness. None of them result in endocrinopathies.

The paragangliomas or chromaffin cell tumors are the most significant of the medullary group. It is with these rare tumors that nonnephritic paroxysmal, or intermittent, hypertension has been reported. This clinical syndrome (which is characterized by recurrent attacks of marked hypertension, although in the interim the blood-pressure may remain quite normal), is due in all probability directly or indirectly to the excessive secretion of epinephrin or some allied compound. The tumors are usually benign and do not produce cachectic states. Wiesel[9] called attention to the vascular sclerosis due to this type of tumor in a child aged two years. A few instances of cure resulting from removal of the tumor have been reported.

"In a study of the cases reported in the literature of tumors of the suprarenal gland, the complexity of the whole problem is especially striking. There are many cases in which the clinical and pathologic data seem to indicate involvement of some particular portion and even some type of cell, and the diagnosis is definite and clean cut. In other instances the complexity of the clinical picture would seem to point to involvement of both the medulla and cortex."[10]

SECRETIONS OF THE SUPRARENAL CORTEX INFLUENCE THE DEVELOPMENT OF THE SEXUAL SYSTEM

There can be no reasonable doubt that the secretions of the suprarenal cortex exert a powerful influence upon the development of the sexual system. Numerous cases of tumor of the suprarenal cortex have been reported, uniformly associated with marked changes in bodily development, and anomalous sex manifestations. Depending on the age in which the disease arises, the glandular manifestations vary. Thus, if the influence of the cortical growth with its excessive function begins during prenatal life pseudohermaphroditism results, while in the group in which the hyperfunction originates in early childhood, prior to puberty, the syndrome of pubertas praecox develops. A third type, occurring only in the adult female, is associated with virilism. Several instances of pseudohermaphroditism resulting from or at least associated with bilateral hyperplasia of the suprarenals or with ectopic suprarenal rests, have been reported. It occurs more frequently in the female and consists in a marked overgrowth of the clitoris with concomitant suppression of growth of the uterus and ovaries. However, we have seen recently at the University of California Hospital what was supposed to be a boy of two years of age, who externally had what seemed to be a small penis, with the urethra in the normal position, and below it an empty scrotum. An exploratory laparotomy revealed the presence of ovaries, tubes and uterus. At autopsy this patient was found to have a bilateral suprarenal cortical hyperplasia.

No satisfactory treatment has been devised as yet, although the recent interest in adrenal surgery may, by partial adrenalectomy, provide an opportunity for normal femininity to develop by removing the masculinizing impulse.

TUMORS OF THE SUPRARENAL CORTEX

Tumors of the suprarenal cortex developing in childhood produce a premature growth and ripening of the entire organism. A large proportion of these cortical tumors have been found in females. However, Lisser,[11] after carefully searching the literature, found eight unquestionable instances of adrenal cortical tumors in boys causing sexual precocity. After reporting a ninth case, and the only one of this kind in which the tumor was successfully removed, he adds that two additional cases very likely may fall in this category. Freedman[12] has adequately discussed the differential diagnosis from pineal tumors and tumors of the gonads. The former (pineal tumors) always occur in boys and uniformly result in excessive height and rapid physical development, whereas the latter in most instances are found in girls. In fact, most of the cases of precocious puberty in girls have been found due to ovarian growths, probably granulosa cell tumors. Hyperfunction of the internal genitalia, with consequent abnormally early menarche, is usually associated with this type of tumor. Premature onset of the menstrual cycle points to pathologic involvement of the ovaries; suprarenal cortical tumors are more apt to produce hypertrophy of the external genitalia. In addition, there seems to be a "tendency to the development of the male at the expense of the female characters in the girls (virilismus), and an intensification of the male characters in the boy (pubertas praecox virilis)." Girls are masculinized, as is exemplified by the growth of beard and mustache, hair on the chest, upper thighs and abdomen and by hypertrophy of the clitoris, deepening of the voice and a masculine bodily configuration. Menstruation is usually absent, although in certain cases in which cortical tumors have been found there has been early female sexual development with the onset of menstruation in early childhood.

Boys of four or five may have the external genitalia of the adult, as in Lisser's case, with abundant hair on the mons pubis, in the axilla and on the upper lip and chin.

The accelerated development is not restricted to the sexual domain or secondary sex characters, but is accompanied by advanced ossification, dentition, bone growth, unusual muscular strength, and adiposity. The development of the psyche does not, as a rule, keep pace with the rapid bodily growth and maturity in contrast to the astonishing maturity of thought, mind and speech said to be associated with the rare instances of macrogenitosomia praecox resulting from pineal tumors.

It is the recognized association of hirsutism and virilism with adrenal cortical tumors which has resulted in the suggestion that yet another hormone may be secreted by the cortex, since excesses of the cortical hormone as it is at present known can hardly be held responsible for this syndrome. As a matter of fact, our present knowledge of the physiology of the adrenal glands is in many respects quite primitive. Undoubtedly new researches will, in time, clarify the present chaotic mass of information now at our disposal. For the present, however, it is felt that a brief review of this type should concern itself only with variations from the normal which can be ascribed with reasonable certainty to abnormal function of the adrenal glands. Finally, it should be mentioned that in as much as consideration has been given only to those conditions for which we have rather definite evidence that alteration in activity of either the medulla or cortex of the adrenals is the morbific factor, no attempt has been made to analyze the rather voluminous literature which has accumulated on the subject of adrenal dysfunction.

DISCUSSION

Rieta C. Hough, M. D. (1212 Medico-Dental Building, San Diego).—Doctor Shepardson has covered the subject so thoroughly that relatively little is left to say. However, there are one or two points which may be noted.

The adrenals contain more vitamin C in the form of "ascorbic acid" or, as it has more recently been called, "cevitamic acid," than any other gland in the body. Experiments on rats indicate that scurvy is a dysfunction of the adrenals. Probably the improvement in patients with malnutrition who have been fed adrenal compound may have been due as much to the ascorbic content as to the gland itself.

The relation between the adrenals and sodium metabolism has definitely been brought out, patients with Addison's disease are greatly improved by the addition of large amounts of sodium chlorid to their diet, and the dosage of cortin required varies with the sodium chlorid intake. Recently it has been reported that adrenalectomized animals have been kept alive indefinitely by the giving of sodium chlorid and sodium bicarbonate, or sodium chlorid and sodium citrate without the use of cortin; if this proves satisfactory in humans, it will be a boon to the patients with Addison's disease.

The suggested use of cortin in cases of bronchial asthma, glaucoma, mastoiditis, low blood pressure, generalized weakness, etc., indicates that our knowledge of adrenal function is limited, and that the study of this gland still offers a large field for research.

⁂

Frank Hinman, M. D. (384 Post Street, San Francisco).—These conditions, which have been so fully described by Doctor Shepardson, open up an entirely new field in surgery. The great possibilities in the surgical correction of pseudohermaphroditic anomalies were presented recently in a striking manner by Doctor Young, who has done pioneer work in this field.

There are two aspects for consideration: First, discovery and correction of the endocrine disturbance; second, surgical repair of the anomaly of development which this disturbance has produced. Confusion will arise in the correct interpretation of the endocrine disturbance, because of the close interrelations of the activities of the pineal, pituitary and thymus glands, and the gonads with those of the adrenals. Cryptorchids occasionally are found to be pseudohermaphrodites. The sexual syndromes arise from the adrenal, through changes in the normal activity of the interrenal component (cortex). When hyperactivity occurs in fetal life (usually in females), it produces pseudohermaphroditism; when in fancy (usually in males), it produces precocity; and when it occurs after puberty (usually in females) hirsutism and masculinism result. The pathologic change in the adrenal gland, associated with these various syndromes, is an increase in the number of cortical cells either in the form of a circumscribed adenoma, of diffuse adenomatous nodules, or of uniform hypertrophy. Sometimes these changes cannot be recognized by the surgeon even after full exposure of the glands. The circumscribed adenomas, as in Lisser's case, will displace the kidney downward and outward, a well-marked characteristic of adrenal tumors which is demonstrable pyelographically. The other forms of cortical hyperactivity give no urologic indication—no tumor is demonstrable, pyelograms are normal, and the diagnosis must be made on the strength of the genito-adrenal syndrome alone. Exploratory operation is indicated. If there has been no clinical evidence of the side on which a possible adenoma may be present, and exposure of one gland reveals apparently normal tissue, it is well not to close the wound until after the other gland has been inspected; because, if it also reveals no adenoma and is normal in appearance, the indication is for partial resection of both glands. In two such instances in my own experience, subsequent microscopic study of the resected portions revealed hypertrophic nodules as the cause of the cortical hyperactivity. This is just one of the types of surgery applicable to the first aspect of the problem: correction of the primary endocrine disturbance. It may be all that is required surgically.

The many interesting types of surgery applicable to the repair of the various maldevelopments caused by excess hormonal activity and deficiency cannot be more than mentioned in this discussion. This second aspect of the problem, however, is as important as the first. The remarkable case of Doctor Young's patient with true hermaphrodism (both testis and ovary), in whom masculine characteristics were made predominant by removal of the female structures and repair of the male, is an example of what can be done surgically in this new field.

⁂

Francis Scott Smyth, M. D. (University of California Hospital, San Francisco).—The great temptation to let fancy roam when discussing problems of endocrinology is altogether too frequent in medical literature. Doctor Shepardson has, however, clearly presented only what is known, and has shown great restraint in discussing the confusion of clinical application. I dare say that it might have been easier for him to have limited his treatise to a lengthy review of experimental work, or to have indulged in a flight of ideas in discussing detailed case studies. However, he has avoided both extremes. Those of us who have seen some of the patients to whom he refers, and have likewise benefited from Doctor Lisser's pioneer interest in the field, can realize how valuable is persistent study linked with healthy skepticism.

ELECTROCARDIOGRAPHY: ITS VALUE TO THE GENERAL PRACTITIONER*

By H. M. F. Behneman, M.D.
San Francisco

Discussion *by Lewis Gunther, M.D., Los Angeles; John J. Sampson, M.D., San Francisco.*

In presenting this paper on electrocardiography, I realize fully that you have come here tonight for an exchange of ideas having some definite practical value in your daily work. Matters of purely scientific or academic interest, as well as the late developments of the various specialties, can be reviewed by you from the multiple medical journals in circulation. I am fully aware of the time element that must play a major rôle in a medical practice such as yours, with its wide geographical distribution. You, however, are interested as much in practical aids to diagnosis as the patient is in treatment. So it is, with these things in mind, that I accept your kind invitation tonight to discuss a subject that has been gradually establishing a place for itself in the practice of medicine, but of which a large number of physicians have not been able to develop a working knowledge.

Heart disease still remains, and by a fairly good margin, the leading cause of death in this country. A good percentage of these cases of heart disease come under the grouping of the cardiac irregularities.

PRACTICAL VALUE OF AN ELECTROCARDIOGRAM

The question in your minds tonight, then, is this: Of what practical value is an electrocardiogram? My answer is threefold. First, the electrocardiogram has given the practitioner greater knowledge in the diagnosis of cardiac disease. Secondly, the electrocardiogram has rendered prognosis more accurate; and, lastly, it has rationalized therapy to a great extent. I ask you to think of cardiography as you would roentgenology: in other words, as an adjunct to various other diagnostic methods, principally those of physical diagnosis. Cardiography does not displace any of our other methods, such as history taking, inspection, percussion, auscultation, roentgenology, and laboratory work. The diagnosis of a patient's malady should no more be made solely from a cardiogram than from an x-ray. It may confirm, however, the same as does an x-ray, our suspicions when we have limited our diagnostic possibilities to a narrow margin and need help in their elimination.

HISTORY OF GRAPHIC METHODS

Taking just a few moments for a very brief mention of the history of this subject, I bring first the name of Einthoven of Holland, who was really the father of this subject by the introduction of his string galvanometer. We already knew from the old frog-heart experiments, particularly those of Müller in 1856, that the contraction of heart muscles resulted in the production of differences in electric potential. Then Waller, in 1887, demonstrated that these differences in potential could be recorded, but the instrument he used was totally inadequate, being a capillary electrometer. Now this more sensitive instrument enables us to reap the benefits of graphic methods.

PHYSIOLOGIC PHASES

Now, a few words concerning the physiologic phases of electrocardiography. We know that the successive contractions of auricles and ventricles are due to the passage of an electrical wave of excitation which precedes the contraction of the heart chambers so stimulated. We know that this impulse seems to originate in muscle tissue comprising the sino-auricular node, also called the pace maker. From this pace maker, the stimulus spreads rapidly over the right auricle, much as a pebble spreads waves when it is dropped into water. From the right auricle it goes to the left, then to the ventricles through the auricular-centricular node and down the bundle of His, into its right and left branches, and on to the network of fibers lining the walls of the ventricles.

Now it has also been long known among physiologists that if two electrodes are placed on an uninjured cell no deflection of the galvanometer can be detected; but in the case of an injured cell a difference of potential is developed between injured and uninjured regions. It is upon this physiologic basis that electrocardiography rests. The record we finally obtain, therefore, represents the algebraic results of these electrical stresses occurring from time to time in the direction of the plane employed. The active heart is just an electric battery surrounded by a large mass of conducting medium, which varies in potential and in the position of its poles during each cardiac cycle, thereby giving rise to the various waves of the electrocardiogram. It also pictures the time relation of the spread of these currents as well as their direction.

ESSENTIALS OF THE TECHNIQUE

The technique can be shown you in a few moments. Suffice to say here that this technique consists merely in the photographic registration, on a moving-picture film, of the movements of a reflected beam of light coming from a mirror properly mounted in an electromagnetic field, and caused to move by small changes of electric potential that enter from the electrodes which are attached to the body surface of the subject. You know, as well as I, that whenever any muscle contracts it develops an electric potential; but when we have the body completely at rest all muscles are perfectly inactive except those of respiration and the heart. The electrocardiogram then becomes a concise graphic record of the electrical activity of the heart which we are examining. There are three graphic results on each tracing which we call leads. Lead one is the electrical potential picked up in the horizontal plane from left wrist to right wrist. Lead two is that received in an oblique plane from right wrist to left ankle, and lead three is the result obtained in the vertical plane from left ankle to left foot. I shall not take your time to go over the subject of the interpretation of these tracings. At the conclusion of this paper, however, I shall show some slides of normal and pathologic tracings which I am sure will be of interest to you. At that time I shall explain some of the fundamentals of their interpretation.

---

* Read before the Humboldt County Medical Society, Humboldt, September 18, 1935.

"The irregularities of the heart often confound the physician. The electrocardiogram is the final court of authority in all these cardiac irregularities. Frequently, thorough physical examination is all that is required for diagnosis. But at times certainty is possible only by employing graphic methods, and even then, as in autopsies, the diagnosis may occasionally fail to be clear. . . . "[1]

ELECTROCARDIOGRAPHY AIDS IN UNDERSTANDING OF DEFECTS IN CARDIAC MECHANISM

Once the simple facts of an irregular pulse have been ascertained, our interest naturally inquires further to ascertain what cardiac mechanism is behind this irregularity; because the management, the therapy and the prognosis often depend upon the nature of this disturbance. Let me give a few instances. Sinus arrhythmia, probably the commonest of all cardiac irregularities, is quite prominent in some individuals, and nearly absent in others, and usually has no pathologic significance. If, however, ordinary sinus arrhythmia is complicated by the presence of extrasystoles, it is often confused with auricular fibrillation, certainly a condition resulting from serious organic heart disease with an equally serious outlook. Similarly the significance of common extrasystoles is far different from that of auricular fibrillation. Moreover, extrasystoles which come from multiple foci are more serious than those arising from a single focus. We know that when we get any ventricular extrasystoles these may be a warning of usually fatal ventricular tachycardia, or ventricular fibrillation. Another instance where it is important from the standpoint of treatment and prognosis to differentiate, is the diagnosis between auricular fibrillation and partial heart-block, wherein there are occasional dropped beats. The sound at the apex and the feel at the wrist is practically the same in auricular fibrillation as it is in partial heart-block, where there are dropped beats. However, our treatment is radically different, as is the prognosis. Digitalis and quinidin are of great benefit in the treatment of auricular fibrillation, whereas we would tremble to use it in even moderate heart-block, for fear of inducing a partial block to become a complete one, an extremely serious condition.

INTERPRETATION OF CERTAIN PALPITATION CASES

And now I would like to mention a condition frequently seen by the internist with somewhat marked subjective symptoms, but with a physical examination that almost leaves one at a loss as to the etiology of the patient's complaint. This is the type of individual who comes in sometimes in youth, but usually in middle age or later, with a complaint of shortness of breath or palpitation on almost the least exertion. Our history may help us if there has been rheumatic fever. If not, the history may be worthless. Our physical examination may not reveal any cardiac pathology by all of our physical methods, nor does the x-ray reveal any pathologic hypertrophy. We take our electrocardiogram and find a very interesting situation. We can see at a glance that through some previous destructive factor the conduction time between the auricle and the ventricle is markedly delayed. This is definite heart-block, a mild form early in the game, but the forerunner of serious myocardial involvement or more complete block as time goes on. Therefore the clinical recognition of milder forms of heart-block is difficult, and quite impossible without graphic methods. This prolongation of conduction time between the auricle and ventricle is one of the early manifestations of rheumatic heart disease, or any other disease process resulting in sclerosis or destruction of the conduction fibers. A block between the auricle and ventricle, if complete, can be recognized by the pulse rate, but if partial it can only be differentiated with the aid of an electrocardiogram. We see many patients with a pulse rate of 50, 55, 60; in other words, an ordinary bradycardia for which outside factors have been blamed, such as gall-bladder disease, vagus stimulation, and so forth. The vast majority of these people show, when a cardiogram is made, that they have a heart-block of varying degrees, and that we are having as many as two or three auricular beats to every one of the ventricle; but there is no irregularity at the wrist because the ventricle is beating slowly and evenly, but it is a serious condition with a serious prognosis if let alone.

CARDIOGRAM FURNISHES GRAPHIC EVIDENCE OF MUSCLE INVOLVEMENT

Now next in importance as a diagnostic aid in the irregularities and the partial and complete blocks, the cardiogram is distinctly valuable in giving us graphic evidence of muscle involvement. As previously mentioned, severe myocardial damage can be diagnosed from the history and physical findings without a cardiogram, but the degree of that damage cannot be accurately known without one.

Moreover, there are three definite instances in which this graphic evidence is of fine significance, without any reference to the physical findings of the patient. These are recent coronary occlusion, overdigitalization, and bundle branch block. However, we cannot state unconditionally that the degree of abnormality in a cardiogram always parallels the amount of cardiac damage, since the heart, like the brain, has many silent areas. However, the electrocardiograph does record *every* change in the functional capacity of the heart, and it will record changes in the anatomy of the heart if these changes have advanced enough to disturb its function.

VALUE IN TREATMENT OF CARDIAC IRREGULARITIES

Also, the electrocardiogram aids definitely in the treatment of irregularities by serving as an important aid in following the extent and recovery from coronary occlusion, and by indicating the stage of digitalization reached in a patient being observed. Without a cardiogram, in your treatment or mine of auricular fibrillation, we may induce so many extrasystoles by the use of digitalis that we may convert an auricular fibrillation to a perfectly normal mechanism; but our extrasystoles that we have induced may lead us completely astray, leading us to believe that the fibrillation still exists when it does not, with the result that we mistakenly push the digitalis still further. A cardiogram shows us our error instantly.

THE CYCLE OF A NORMAL TRACING

Now before showing the slides of a few interesting cases I wish to draw one diagram, a simple one which, if you will keep it in mind, will give you the basic standard behind the interpretation of all tracings. Let me draw one phase of the so-called cardiac cycle; in other words, one complete cycle of a normal tracing. Please try to keep this normal in mind when I show these pathologic tracings, and you will see the distinct difference in them and in their significance to the interpreter. The different waves recorded for each cardiac cycle are labeled with certain letters of the alphabet. The letters themselves do not stand for any particular words; they were merely picked at random. They are known as the P, the Q. R. S., and the T waves. Looking at the normal cardiac cycle, which I have drawn here, this wave, the P wave, is the wave related to the contraction of the auricle. The next wave, the Q. R. S. complex, is the wave of ventricular contraction. The final wave, the T wave, represents the end of the ventricle contraction and is the process of relaxation or diastole of the heart. Now our particular concern, also, is the distance between the beginning of the P wave (or the auricular wave), and the completion of the ventricular contraction. Another interval of interest and significance is the time between the end of the ventricle contraction and the end of its period of rest, until it starts over again. The third point of interest is the height and width and direction of these curves. There is a mathematical standard normal of time, of height, of distance, and of direction. Every change in every one of these four factors is of significance to the interpreter. They may be pathologic or they may not be. I am going to project a few slides of characteristic tracings so that you can see the marked deviation from normal that occurs in some of these tracings. I ask that you remember that there is little room here in the interpretations of these cardiograms for individual opinions, such as in the interpretation of an x-ray film. Electrocardiograms are algebraically correct and mathematically standardized. After these slides have been projected, I have six slides showing the chief reasons for your consideration of a wider use of the electrocardiographic means at your disposal in this community.

SUMMARY

In conclusion, so far as the text of this subject goes, just previous to the slides, may I once again answer the question: What has the electrocardiograph to offer the general practitioner? It has these fourteen important aids:

1. The recognition of auricular flutter, a serious pathologic heart condition.

2. It gives us the differentiation between auricular fibrillation and multiple extrasystoles.

3. It differentiates for us auricular from ventricular paroxysmal tachycardia.

4. It also differentiates between regularly occurring extrasystoles from partial heart-block.

5. One should hesitate to ascribe such symptoms as shortness of breath, palpitation, rapid heart, fatigue or chest pain, that is not typically anginal to heart diseases unless it can be demonstrated that the heart is abnormal. The real trouble may be secondary anemia, or pulmonary lesions, or perhaps a psychoneurosis. In such cases a distinctly abnormal tracing greatly increases the probability that no mistake can be made in attributing the symptoms to myocardial damage. In the course of an attack of rheumatic fever, and less often in the course of some other acute febrile illness, cardiograms may show evidence of myocardial involvement when other signs that the disease has attacked the heart are completely lacking.

6. In essential hypertension, changes in the heart are frequently detected by the electrocardiograph before cardiac signs and physical symptoms develop.

7. Cases of suspected angina pectoris, having normal electrocardiograms, substantially increases the probability that the tentative diagnosis is correct.

8. In coronary thrombosis the electrocardiogram is usually very characteristic and usually far more helpful than the physical examination of the heart, which is often entirely negative. You have all seen the wide variation in the pain of coronary disease. When it is abdominal, and surgery is in the offing, a cardiograph is of infinite value in the characteristic picture it usually gives us.

9. The electrocardiographic changes sometimes persist for years after the occurrence of myocardial infarcts, and in rare instances the cardiogram furnishes the only available evidence that an infarct has taken place.

10. Control of the administration of digitalis is desirable whether this drug is given rapidly or continued to the limit of tolerance. This is possible by means of occasional electrocardiographic examinations.

11. The electrocardiographic control of intensive treatment of auricular flutter or fibrillation with quinidin is almost imperative.

12. Last, but not least, it can detect myocardial disease at times when all other methods fail. For various reasons of travel, exertion, livelihood, legal aspects, etc., one often wants to know, if myocardial damage exists, how severe it is. The cardiogram is the final court of authority.

13. It is of value in prognosis.

14. It is of value in determining the present status of a patient for surgery, as well as his cardiac resistance to disease and his cardiac reserve.

It is fair to say that a cardiovascular examination is not complete without an electrocardiogram. I do not presume to persuade you, on the other hand, that it has magical, errorless, impossible powers. But it is an invaluable adjunct to our diagnostic armamentarium. It can give us important information that neither the hand nor the eye nor the ear can discover.

DISCUSSION

Lewis Gunther, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Behnemann's paper shows the value of the electrocardiogram in detecting irregularities of the heart rhythm, and also hidden subclinical diseases of the ventricular muscles.

The greatest value of the electrocardiogram lies in its ability to teach the clinician the manner in which he may train his finger, his eye and his ear to detect the irregularities at the bedside. After a period of time, where close check is made on the clinical studies by electrocardiograms, the clinician may learn to accurately diagnose, or strongly suspect, more than 90 per cent of these irregularities, without having to resort to mechanical aids.

A situation in which the electrocardiogram, by giving collaborating evidence, proves itself to be a great teacher in clinical and bedside medicine, occurs in certain types of acute pericarditis, following acute upper respiratory infections with or without concomitant rheumatic fever. Patients in this group complain of a vague illness, consisting of malaise, perhaps a little fever, excessive rapidity of the pulse on the slightest exertion or physical activity. There are almost no physical findings, but still there exists a disability so far out of proportion to what the doctor finds clinically at the bedside, that one may be rightly puzzled at the validity of the patient's complaints.

However, detailed attention to auscultation at the base of the heart with the *Bell* stethescope, using adequate and forcible pressure on the skin, will often detect a faint, rather high-pitched short systolic crackling friction. This friction is sometimes easily audible, and sounds like the to-and-fro crackling noise produced when the corner of a sheet of very stiff paper is bent back and forth between the thumb and forefinger. The result of the electrocardiogram in such instances shows a striking inversion of the T waves, sometimes in all three leads, and the waves are often characteristically curved as in the Pardee coronary T wave. However, these patients rapidly resume a normal electrocardiogram after a week or ten days in bed, and thereafter rarely show evidence of disease of the ventricular muscles.

There is a tendency among many physicians to administer digitalis in heroic doses to any patient who has a rapid and regular pulse, as well as to those whose pulse is irregular and rapid. And when the patient vomits, the procedure seems to be to force it into the system by intramuscular injection. In the occasional patient who is sensitive to digitalis the danger is great. When patients with regular rhythms are closely followed by serial electrocardiograms under digitalis therapy, much to one's surprise it may be seen at times that full digitalization effect is seen on the T wave of the electrocardiogram, when only one-half of the calculated Eggleston's dosage has been administered.

In the experience of the writer it has not been unusual to find a patient with a well-developed ventricular tachycardia who has been given a full calculated digitalis dosage in a short period of time. Under these circumstances the writer has found it almost impossible to reverse the fatal tachycardia. It may be open to question as to whether or not the digitalis poisoning produced that particular episode; but it is a well-known fact that digitalis intoxication may result in a fatal ventricular tachycardia.

Therefore, in this writer's opinion, it is of utmost importance for the welfare of the patient that the general practitioner should acquaint himself with the exact mechanism of the rapid pulse by taking an electrocardiogram before such digitalis therapy is commenced. The delay occasioned by the procedure of taking an electrocardiogram when there is even the slightest question of the accuracy of the bedside diagnosis of the tachycardia, is far less serious than the routine use of digitalis in every rapid pulse rate.

In conclusion, therefore, the writer would again like to emphasize that the value of the electrocardiogram, as a teacher to the bedside clinician, cannot be overestimated.

⁂

John J. Sampson, M. D. (490 Post Street, San Francisco).—The essayist has well outlined the numerous instances in which the electrocardiogram is of value to the practicing physician. Our outlook on the situation in 1935 is altered materially from that of ten years ago, when the only means of taking an electrocardiogram was with the large cumbersome machine to be had only in hospitals. Many portable models are now available that enable us to carry the study of certain problematic cases to completion at the patient's bedside, and this is especially true of acute coronary artery occlusion.

Unfortunately, interpretation of electrocardiograms is not always a very simple matter. Whereas characteristic pictures, such as deep inversion of T waves or the common forms of auricular fibrillation and ectopic beats, may be readily diagnosed with little training, border-line deviations from the normal are very likely to be either over- or underemphasized as to their clinical importance, without quite a reasonable amount of associated clinical and electrocardiographic experience. Often the slight deepening of Q waves, and depression or elevation of S-T intervals, may be the sole determining elements in establishing a diagnosis of acute coronary artery occlusion. On the contrary, slurred S waves and S-T intervals commonly occur in normal individuals, and are frequently misinterpreted as evidence of heart-muscle damage.

One must be cautious in reading too much of the clinical state of the patient from the electrocardiogram. After all, it is only a record of the nature of the excitation and contraction wave in passing through the heart, and tells practically nothing of the circulatory dynamics. It is not unknown to find individuals with organic heart disease involving one or more valves, and even with congestive or anginal heart failure, who have absolutely normal records although this occurrence is rare. Likewise, it is no more necessary to rush to the taking of an electrocardiogram on every case of heart disease where the diagnosis of anatomical and functional disturbances are clear than to take blood counts on every characteristic acute common cold.

Several years ago we estimated, in the laboratory of the University of California, that at least 80 per cent of the patients on whom electrocardiograms had been taken for either heart-muscle damage, arhythmia or miscellaneous disturbances such as pericarditis, were adequately diagnosed clinically prior to the taking of records. Thus, whereas I quite agree with Doctor Behnemann as to the many uses of this valuable technique and its absolute necessity in certain instances of heart disturbances, I must admit we should be well able to do without it in many instances if we use our clinical diagnostic and prognostic abilities.

CANCER OF THE RECTUM*

By William H. Daniel, M.D.

Los Angeles

Discussion *by Montague S. Woolf, M. D., San Francisco; William H. Kiger, M. D., Los Angeles; James W. Morgan, M. D., San Francisco.*

It is never amiss, in discussing cancer of the rectum, to emphasize the early symptoms, the disregard of which so often allows a curable case to become incurable. The most common are bleeding, which may occur late; change in bowel function, such as constipation or frequency; loss of weight; discomfort and pain. Many of these cases have been treated for colitis, amebiasis, injected for hemorrhoids, or subjected to colon irrigations without digital or proctoscopic examination, by which 100 per cent of these lesions are demonstrable. The negative barium enema should not be regarded as diagnostic, since the majority of tumors of the rectum do not show a filling defect. It is unfortunate that the majority of the rectal cancers occur in the silent roomy ampulla, or the rectosigmoid, and are not suspected until extension to adjacent or distant organs has taken place, or the systemic effects are such that a radical operation is hazardous.

---

* Read before the General Surgery Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

BIOPSY

It is believed that cancer of the rectum begins in the mucosa, and that adenomata, and polypi, especially those with a broad base, are potential carcinomata. Microscopic examination of tissue is indicated to confirm the diagnosis, and to determine the grade of malignancy. A negative report is a demand for another biopsy, especially if the growth feels and looks like cancer.

INDICATIONS FOR OPERATION

Operability depends upon many factors, the most important of which are: the condition of the patient, and the experience and ability of the surgeon. A rectal cancer should be considered operable when it may be removed in its entirety, without unduly jeopardizing the life of the patient; or when, even in the presence of moderate metastases, its removal will prolong the life of the patient with mental and physical comfort.

The majority of these patients are between the ages of fifty and seventy-five years. Radical one- or two-stage operations must be considered with care in those over sixty. In those under thirty, all methods of treatment are usually inadequate, and the most radical procedure is indicated.

Moderate metastasis in the liver does not forbid surgical removal of the tumor. The patient who knows his cancer is gone is much more comfortable and hopeful.

The welfare of the patient is the chief consideration in the treatment, which has as its object the complete eradication of the disease, or the maximum extension of useful life with mental and physical comfort. The surgeon should not have a fixed rule as to choice of operation, but should be guided by the physical and laboratory findings. He should not attempt to treat all cases by any one method, as no one procedure is applicable in all cases. The tumor may be small, low, and movable, and yet be highly malignant. The size of growth is no indication of metastasis. The lesion growing into the bowel wall is more prone to metastasize than one extending into the lumen. A growth may be easily resectable, but the condition of the patient, or the presence of metastases, make the effort useless. The condition of the heart and blood pressure may contraindicate suitable anesthesia and a prolonged surgical procedure.

CHOICE OF SURGICAL PROCEDURES

After the patient has been put in as good condition as possible, the surgeon must then choose the procedure which, in his opinion, offers the most for that particular patient. The five most common surgical methods are: (1) Abdominoperineal resection of the sigmoid and rectum in one or two stages; (2) colostomy and perineal resection; (3) colostomy and posterior excision; (4) local excision; (5) colostomy, palliative only.

The abdomen should be explored, unless there is some definite contraindication, to ascertain the presence of metastases. A colostomy is always indicated unless the growth is low and small, and of low malignancy, and local resection offers a reasonable chance for cure. An incontinent rectum is much more disagreeable than an abdominal anus. The colostomy patient should not be an object of pity, for he quickly becomes accustomed to the slight inconvenience. A selected diet makes its care fairly simple.

SURGICAL PROCEDURE MUST BE SUFFICIENTLY RADICAL

To be successful, every procedure must be sufficiently radical to remove all the growth and lymphatic channels. The abdominoperineal resection of the sigmoid and rectum is the ideal procedure, because more of the lymphatic structures are removed. Although the mortality rate may be higher, the possibility of recurrence is less. The one-stage operation is the most ideal, if the risk to the patient is not too great. The percentage of operability is much less than in the two-stage operation. The two-stage method is much less dangerous, since the patient has a chance to recover from the colostomy operation, before the more drastic procedure is undertaken. Bowel function is restored, the patient's food and water intake become more normal, and the inflammatory process about the tumor may subside, allowing safer removal. If there is any marked degree of obstruction, or the growth large or fixed, the two-stage method is the one of choice.

The colostomy and posterior resection method is favored when the growth is low and the patient a poor risk or advanced in years. Perineal excision without colostomy has been discarded by most surgeons as being inadequate. In some medical centers in Europe, posterior excision with perineal anus is still the method of choice. Local excision with cautery is satisfactory in a very limited field. Recurrences are common, because ordinarily the lymphatics within the peritoneal cavity are not removed.

ADENOMATA AND POLYPI

Adenomata and polypi, no matter how small, should be regarded as possible cancer, a section taken for microscopical examination, and the tumor treated thoroughly with the cautery. In cases of malignant polypi, the question arises whether to perform radical operation or to attempt local removal. If the mass is small, and movable, treatment with the cautery may be sufficient. On the other hand, this procedure may be wholly inadequate because metastases may already be present, or the cancer cells may have extended beyond reach of the heat. If it is reasonable to assume that invasion of other tissue has already begun, radical operation is indicated. The question is a difficult one to answer, and the surgeon may have cause to regret either procedure that he may select.

RADIATION THERAPY

Radiation in all its forms is still a matter of controversy. The value of radium has been a topic of disagreement for many years. Binckley states that the treatment of rectal cancer remains a surgical problem, but radium and deep-radiation are important aids to surgery.

ANALYSIS OF AUTHOR'S CASES

The foregoing opinions have been formulated from a study of a large number of articles in the literature dealing with this subject, and from examination and observation of approximately 240 cases. More than one-half of this number were treated personally.

There were twelve patients, or 5 per cent, below thirty years of age, and twenty-seven, or 11 per cent, below forty years of age. In this group only three below thirty years were operable, and only two are living. There are five living below forty years of age. All of these had the abdominoperineal resections. The remainder were either inoperable when seen, or had a recurrence from a previous operation. Practically all in this group were of high-grade malignancy. Sixteen per cent were over seventy, and 40 per cent over sixty, leaving 50 per cent in the most favorable period, from forty to sixty years of age.

There were 158 biopsies recorded, and 120 were graded as follows: low—9 per cent, moderate—33 per cent, and high—58 per cent. Adenocarcinoma occurred in 91 per cent, epidermoid in 6 per cent, and 3 per cent were undifferentiated. Metastases were present, as a rule, in the high grade, though there were several in the moderate group. In several cases, it was necessary to do repeated biopsies, at times surgically, to make a positive diagnosis. Specimens of the same tumor may vary in grade. One biopsy was reported as Grade I, and a block from the surgical specimen was reported as Grade IV. We believe that the grading of tissue is of benefit in the prognosis as to recurrence, and in the choice of operation. The higher the grade, the more radical should be the procedure. Recurrences occurred usually in the high grades. In the whole group, according to available information, there have been nine recurrences from local and perineal excision, and two from abdominoperineal procedures.

There is an apparent variance between our operability figures and those reported in large clinics. Perhaps it is because there are more quacks, cults, and fake cures, in Southern California than elsewhere. In the clinic cases, only 35 per cent were operable, and in the private cases, 60 per cent operable. Estimated operability in the group as a whole compared closely with operability determined by exploration, namely, 45 per cent operable, and 55 per cent inoperable.

Experience with those patients having had deep radiation was limited. The results were disappointing, to say the least, the chief one being an unnecessary postponement of an inevitable demise.

There were several secondary involvements of the rectum from cancer of the cervix and prostate, and four which were considered to be implantations from carcinoma of the stomach.

The following procedures have been carried out: abdominoperineal, 22; colostomy posterior resection, 17; colostomy posterior excision, 11; local cautery excision, 9; anterior resection, 1; cautery through proctoscope, 8; colostomy, 62. There was a mortality of 16 per cent in the completed radical procedures.

IN CONCLUSION

In concluding, it is the desire to leave the thought that all colon and rectal disturbances, however slight, may mean cancer. The time for cure is in the early stages, and only by conscientious examination may these be discovered. The yearly examination of every person over forty is ideal, but impractical. We should not consider our mortality rate when the welfare of the patient is at stake. It is more justifiable to have a surgical death in the attempt to completely eradicate this disease, than to have a rapid recurrence. In case of failure, the greater service may have been rendered the patient and his family. Sane, radical surgery offers the greatest hope.

1930 Wilshire Boulevard.

DISCUSSION

Montague S. Woolf, M. D. (384 Post Street, San Francisco).—In a short space Doctor Daniel has set forth many items of interest concerning cancer of the rectum. In the past, some patients came too late to the surgeon on account of the referring physician. The latter did not then avail himself of a digital examination, though it was suggested by the complaint. The patient complained of bleeding from the rectum, said he had piles, and was believed. This meant that many a patient suffering from carcinoma was treated on the diagnosis of the patient and, consequently, was allowed to live with his growth until it became inoperable. More recently the referring physician has come to realize that 80 per cent of cancers originating even as high as the rectosigmoid junction can be felt by the examining finger. The remaining 20 per cent could also be diagnosed by a physician, if a sigmoidoscope or a barium enema were used. In other words, the diagnosis of carcinoma of the rectum is not difficult. But still there are numerous patients who come too late to any physician. It is they who have to learn now that bleeding from the rectum can be very much more serious than hemorrhoids, and that only a physician can differentiate between the two lesions. Another reason why carcinoma is overlooked is that the age of the patient and the obstructive lesion in the rectal wall predispose to hemorrhoids. Therefore, the two conditions will more often than not occur concurrently.

Diagnosis must precede treatment, and a poor attempt at the former will lower the operability for cancer of the rectum. Doctor Daniel's operable figure of 45 per cent is too low for us to be satisfied. This figure does not seem to be much over 60 per cent in the very largest centers for this work. It seems important to let the public know not that surgery is still the only treatment of cancer, but that cancer is curable by surgery. This implies that an individual ought to have a complete physical examination at least three times a year, especially when he reaches forty years of age. This part of the subject is one of education. Better-placed individuals are more often cured of cancer than those poorer, and it is not entirely a matter of money. Education teaches an individual the facts of a situation and, more important, helps him to discriminate between them. Bleeding from the rectum, therefore, in one case will mean only "piles," in another many forms of intestinal disorder, among which cancer will be significant.

The primary and recurrent mortality of cancer in any region will, therefore, be lessened as the public becomes educated, and according to the development of expert surgery on the part of the physician. As far as the surgeon is concerned, great progress has been made in the surgical treatment of cancer of the rectum. Of operable cases less than 11 per cent can be the primary mortality in one of surgery's greatest operations, namely, the modern abdominoperineal procedure in one stage. This was formerly over 40 per cent in the hands of the originator. Five-year survivals from this operation are considerably over 50 per cent. The tragedy of the final results lies in the fact that not much over 50 per cent are operable when patients with the disease see the surgeon.

⁂

William H. Kiger, M.D. (1930 Wilshire Boulevard, Los Angeles).—There is one point that Doctor Daniels has mentioned that cannot be stressed too much, and that is, early diagnosis. We know that cancer remains local in this locality longer than anywhere else. There seems to be a lack of appreciation of this fact on the part of many of the profession, and many sufferers from this disease have been allowed to waste months of valuable time because their family physician did not take the trouble to make a digital examination of the rectum. If a patient complains of blood in the stool, it should always be thoroughly investigated. If it is fresh red blood, it is quite sure to come from low down in the bowel; darker, higher up. This examination should be made routinely: first, digital; second, anascope; third, proctoscope; and, if necessary, barium enema, and always the enema before a barium meal. The radical one- or two-stage abdominoperineal is undoubtedly the operation of choice and the one that has given the most satisfactory results. The one-stage is preferable when possible.

There is another point which I think important, and will help these unfortunates to decide to submit to surgery after the diagnosis is made, and that is to overcome their dread of a colostomy. I have heard many patients, and the opinion was concurred by their family physician, say they would rather die than have a colostomy. A good colostomy, properly cared for, gives the patient very little trouble, and they are able to lead their regular lives. Their education requires a little time, and patience on the part of the surgeon, but it is well worth the time to all parties concerned.

⁂

James W. Morgan, M. D. (384 Post Street, San Francisco).—Doctor Daniel's paper emphasizes the importance of early symptoms. At the University of California we spend a great deal of time teaching diagnosis to undergraduate and postgraduate students. We stress thorough investigation. The practitioner does not like to be reminded of his shortcomings, and he therefore resents our constant repetition of the term "adequate rectal examination." In the past six weeks, four patients with *palpable* rectal cancers have been sent to me. I have operated upon all of them, but I feel quite sure that they should have come earlier. Three of them had had local operations, two for hemorrhoids, and one for fistula. I was able to do radical operations for all of these patients, and their outlook is good; but the prognosis would have been much better if they had come in earlier. Forgive me, then, for repeating Moynihan's dictum: "In all cases of pain between the nipple and the knee, examine the rectum."

Except in rare instances, the patient deserves a very radical operation. The small early growth is no exception, for here is our best chance for complete cure. There is still much to be learned about carcinoma of the rectum, but the remarkable improvement in prognosis during the past few years is one of the outstanding accomplishments of surgery. We can now truthfully say that about half of the patients who present themselves early with malignant tumors of the lower colon and rectum can be cured.

HARRISON NARCOTIC LAW[*][†]

DECISION OF THE DISTRICT COURT OF THE UNITED STATES IN: U. S. A., PLAINTIFF, VS. EDWARD H. ANTHONY, DEFENDANT

IN THE DISTRICT COURT OF THE UNITED STATES IN AND FOR
THE SOUTHERN DISTRICT OF CALIFORNIA
CENTRAL DIVISION

UNITED STATES OF AMERICA, Plaintiff, vs.
E. H. ANTHONY, et al., Defendants.
No. 12069-Y, 12070, 12071, 12072, Criminal

Appearances:

Peirson M. Hall, Esq., United States Attorney, by Howell Purdue, Esq., Deputy United States Attorney, Attorney for the Plaintiff.

Ames Peterson, Esq., Attorney for the Defendants.

In four indictments containing sixteen counts returned on August 30, 1934, the defendant E. H. Anthony, a physician, duly licensed to practice medicine in the State of California, and duly registered with the Collector of Internal Revenue for the Sixth District of California, and others were charged with the violation of Sections 1040 and 1044a of Title 26, U. S. C. A., commonly known as the Harrison Narcotic Act. Each of the counts, in effect, charged that the defendant and a certain druggist did sell, barter and dispense unlawfully certain quantities of morphin sulphate, not in good faith and not in the course of their professional practice. The indictments were dismissed as to the druggist. Four conspiracy counts contained in the indictments were also dismissed. A first trial had before the court with a jury, resulted in a disagreement. The second trial was had before the court without a jury.

The evidence upon the part of the Government showed that the defendant had prescribed quantities of morphin sulphate to four known addicts, James E. Jensen, Peter Mayers, William Avery and Joseph Tint, the persons named in the indictments. The times and the amounts were as follows:

In the case of James E. Jensen: June 16, 1934, 125 ½-grain tablets of morphin sulphate (with the direction, "Dissolve and use as directed"); June 19, 1934, 120 ½-grain tablets morphin sulphate (same directions); June 23, 1934, 90 ½-grain tablets morphin sulphate (same directions); June 27, 1934, 115 ½-grain tablets morphin sulphate (same directions); July 3, 1934, 120 ½-grain tablets morphin sulphate (same directions); July 8, 1934, 120 ½-grain tablets morphin sulphate (same directions): July 14, 1934, 120 ½-grain tablets morphin sulphate (same directions); July 18, 1934, 120 ½-grain tablets morphin sulphate (same directions); July 23, 1934, 110 ½-grain tablets morphin sulphate (same directions); July 28, 1934, 120 ½-grain tablets morphin sulphate (same directions).

In the case of Peter Mayers: June 11, 1934, 168 tablets ½-grain tablets morphin sulphate (with the direction, "Emergency L. A. Clinic"); June 18, 1934, 168 ½-grain tablets of morphin sulphate (same directions); June 25, 1934, 168 ½-grain tablets morphin sulphate (with the direction, "Dissolve and use as directed"); July 2, 1934, 168 ½-grain tablets morphin sulphate (same directions); July 8, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 16, 1934, 100 ½-grain tablets morphin sulphate (same directions); July 23, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 28, 1934, 30 ½-grain tablets morphin sulphate (same directions); July 30, 1934, 84 ½-grain tablets morphin sulphate (same directions).

In the case of William Avery: June 11, 1934, 150 ¼-grain tablets of morphine (with the direction, "Emergency L. A. Clinic"); June 14, 1934, 75 ¼-grain tablets morphin sulphate (same directions); July 8, 1934, 20 ¼-grain tablets morphin sulphate (with direction, "Dissolve and use as directed").

In the case of Joseph Tint: June 13, 1934, 120 ½-grain tablets of morphin sulphate (with the direction, "Dissolve and use as directed"); June 20, 1934, 110 ½-grain tablets morphin sulphate (same directions); June 26, 1934, 110

---

[*] From the press of the Los Angeles City Health Department, Los Angeles, 1936.

[†] This decision is given space in the original article section of California and Western Medicine so that it may more easily find its place in the index of medical literature. See also in this issue, comments on page 115.

½-grain tablets morphin sulphate (same directions); June 29, 1934, 40 ½-grain tablets morphin sulphate (same directions); July 2, 1934, 168 ½-grain tablets morphin sulphate (same directions); July 7, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 9, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 13, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 2, 1934, 168 ½-grain tablets morphin sulphate (same directions); July 20, 1934, 84 ½-grain tablets morphin sulphate (same directions); July 23, 1934, 60 ½-grain tablets morphin sulphate (same directions); July 26, 1934, 75 ½-grain tablets morphin sulphate and 1 needle (same directions); July 30, 1934, 120 ½-grain tablets morphin sulphate (same directions).

Dr. Thomas A. Orbison, a neuro-psychiatrist, testifying for the Government, in answer to a hypothetical question, stated that the prescribing of the morphin under the circumstances to these four men and in the amounts given was not proper medical practice. Dr. C. H. Thienes, head of the Department of Pharmacology. at the Medical Department of the University of Southern California, gave a like opinion. They both expressed the view that the ambulatory treatment of drug addicts was not proper medical practice under any circumstances. The testimony of the defendant's witnesses will appear in greater detail in the opinion of the court finding the defendant not guilty.

* * *

YANKWICH: District Judge. (orally, after stating the facts as above.)

When a judge tries a case of this character, unless there be a question of law or the examination of documents which require further study, he should be in a position at the conclusion of the case to announce his verdict. Perhaps it would be just as well if practice allowed judges trying criminal cases without a jury to render their verdict without giving any reasons. However, the common practice has grown up, both in the State and Federal Courts for judges, in determining criminal cases, to state their reasons. Whether it is a good practice or not, I do not know. I have followed it at all times.

I think I followed this case very closely. We have discussed problems of law as they came along. I realize a case of this character is of great importance to the Government and to the defendant. Ultimately the Harrison Act is an important statute. It was passed in 1914. It has been before the Courts on many, many occasions, and has been sustained. It has, in many instances, and in many respects been declared a great success. It has been followed, as a matter of fact, by statutes in various states, supplementing it so as to cover the situations which could not be handled under the Act.

Everyone is satisfied that the Harrison Act has been noteworthy in destroying or minimizing the nefarious traffic in narcotics. It has been very successful in reaching the peddler, who, for many years, has been the great source of illegitimate supply, to such an extent that whether administering the State laws or whether administering the Federal law, judges have drawn the line between the addict who may be found with illegally obtained drugs in his possession and the peddler who, for a consideration, supplies the need and barters upon what has been here declared to be a disease. And in dealing out punishment I think the Courts, as a rule, have distinguished between the two conditions, treating one as a diseased and unfortunate and the other as a mercenary trafficker in drugs.

I am making the remarks to indicate why I consider a prosecution under this Act important from the standpoint of the Government. Ultimately, of course, we have to administer the law as we find it. We go back to the old Latin phrase that the province of the Court is *jus dicere* not *jus dare*; to pronounce the law, as we find it, not to make the law or to give the law.

The prosecution in this case is not the prosecution of a lay peddler but the prosecution of a physician for having trafficked in narcotics. A physician is within the exceptions to the prohibitions of the State statute which is now codified as Section 1044, Title 26, U. S. C. A. The statute itself provides:

> It shall be unlawful for any person to sell, barter, exchange, or give away any of the drugs mentioned in Section 1040 (a) except in pursuance of a written order of the person to whom such article is sold, bartered, exchanged, or given, on a form to be issued in blank for that purpose by the commissioner.

Section 1040, to which reference is made in that section, provides:

> There shall be levied, assessed, collected, and paid upon opium, coca leaves, any compound, salt, derivative, or preparation thereof, produced in or imported into the United States, and sold, or removed for consumption or sale, an internal revenue tax at the rate of 1 cent per ounce, and any fraction of an ounce in a package shall be taxes as an ounce.

The exception which is in paragraph (c) of Section 1044 U. S. C. A. Title 26, says:

> Nothing in this chapter shall apply . . . (1) To the dispensing or distribution of any of the drugs mentioned in Section 1040 (a) to a patient by a physician, dentist, or veterinary surgeon registered under Section 1384 in the course of his professional practice only.

The statute has been sustained as a revenue statute chiefly. And in the various decisions to which reference has been made during the course of the discussion here, particularly in *United States* vs. *Doremus*, (1919) 249 U. S. 86, a majority of the Court sustained the Act upon the ground that it is not an invasion of the province of the State; that it is a revenue measure only and that the moral ends of the statute are incidental only. Mr. Chief Justice Taft, Justices McKenna, Van Devanter, and McReynolds expressed the view, to which they have adhered, that the Act was not a revenue act, was an invasion of the province of the States, and was, therefore, unconstitutional.

I merely am referring to these facts in order to indicate that we must bear in mind the purpose of the Act—that the Act is a borderline statute which must be interpreted in such a manner as to bring it within the constitutional power. And if we depart from it and interpret it either as attempting to regulate the disposition and sale of narcotics or attempting the regulation of medicine, we extend the Act to the realm which the Supreme Court has repeatedly said the Federal Government cannot enter, under the penalty of unconstitutionality.

The Linder case (*Linder* vs. *United States* (1925) 268 U. S. 5) is very important in determining this case. We all seem to agree, whether we read it alike or not, that it determines this case, so far as the law is concerned. I do not wish to refer at the present time to the portions of the Linder case which determine *what*, if any, prescriptions for narcotics a physician may give to an addict. I wish to refer to it for the present for the purpose of pointing out that the moment we assume that this Act *regulates the sale* within the State of narcotics and that it aims to regulate the practice of medicine we must hold it unconstitutional.

In the Linder case, Mr. Justice McReynolds, speaking for the Court, made this observation:

> Obviously, direct control of medical practice in the States is beyond the power of the Federal Government. Incidental regulation of such practice by Congress through a taxing act cannot extend to matters plainly inappropriate and unnecessary to reasonable enforcement of a revenue measure. The enactment under consideration levies a tax, upheld by the court, upon every person who imports, manufactures, produces, compounds, sells, deals in, dispenses or gives away opium or coca leaves or derivatives therefrom, and may regulate medical practice in the States only so far as reasonably appropriate for or merely incidental to its enforcement. It says nothing of "addicts" and does not undertake to prescribe methods for their medical treatment. They are diseased and proper subjects for such treatment, and we cannot possibly conclude that a physician acted improperly or unwisely or for other than medical purposes solely because he has dispensed to one of them, in the ordinary course and in good faith, four small tablets of morphin or cocain for relief of conditions incident to addiction. What constitutes bona fide medical practice must be determined upon consideration of evidence and attending circumstances. Mere pretenses of such practice, of course, cannot legalize forbidden sales, or otherwise nullify valid provisions of the statute, or defeat such regulations as may be fairly appropriate to its enforcement within the proper limitations of a revenue measure. (Linder vs. United States, supra at 5).

Further on in the opinion, referring to the Webb case (*Webb* vs. *United States* (1919) 249 U. S. 96) which Mr Howell Purdue, the Assistant United States Attorney, has mentioned in his concluding remarks, the Court limits the language of that decision which was first interpreted as meaning that *no* prescription to an addict could be justified under the Act, and says:

> The question specified no definite quantity of drugs, nor the time intended for their use. The narrated facts show, plainly enough, that physician and druggist conspired to sell large quantities of morphin to addicts under the guise of issuing and filling orders. The so-called prescriptions were issued without consideration of individual cases and for the quantities of the drugs which applicants desired for the continuation of customary use. The answer thus given must not be construed as forbidding every prescription for drugs, irrespective of quantity, when designed temporarily to alleviate an addict's pains, although it may have been issued in good faith and without design to defeat the revenues.

Further on in the opinion, talking about the Behrman case, also referred to by Mr. Purdue, (*United States* vs. *Behrman*, (1922) 258 U. S. 280) and interpreting some of the language contained in it, the Court says:

> This opinion related to definitely alleged facts, and must be so understood. The enormous quantity of drugs ordered, considered in connection with the recipient's character, without explanation, seemed enough to show prohibited sales and to exclude the idea of bona fide professional action in the ordinary course. The opinion cannot be accepted as authority for holding that a physician, who acts bona fide and according to fair medical standards, may never give an addict moderate amounts of drugs for self-administration in order to relieve conditions incident to addiction. Enforcement of the tax demands no such drastic rule, and if the Act had such scope it would certainly encounter grave constitutional difficulties.
>
> The Narcotic Law is essentially a revenue measure and its provisions must be reasonably applied with the primary view of enforcing the special tax.

In a subsequent case, *Nigro* vs. *United States* (1928) 276 U. S. 332, Mr. Chief Justice Taft, writing the opinion for the Court, in answering certain certified questions by the Eighth Circuit Court of Appeals came back to the subject of interpretation of the Act, saying at page 341:

> In interpreting the Act, we must assume that it is a taxing measure, for otherwise it would be no law at all. If it is a mere act for the purpose of regulating and restraining the purchase of the opiate and other drugs, it is beyond the power of Congress and must be regarded as invalid, just as the Child Labor Act of Congress was held to be, in Bailey, Collector vs. Drexel Furniture Company, 259 U. S. 20.

So we have in these cases the two limitations which the Court has placed upon the Act—two statements which hold the Act must not be interpreted as endeavoring to regulate the local sale of drugs, or as an attempt upon the part of the Federal Government to regulate the practice of medicine.

The Linder case also lays down the rule which, to my mind, is very clear and is made clearer by subsequent cases which have interpreted it—that the Act does not attempt to tell how much a physician may prescribe to an addict. We must bear in mind in reading the Linder case that the Court there was not passing upon a case after trial. The Court was merely dealing with the sufficiency of an indictment which charged one delivery to a person and did not even charge a sale. So that what the Court said about four grains or about a moderate amount, must be interpreted in the light of that fact. In fact, its own language, in interpreting the Webb case, intimates that it does not intend to delimit either the quantity or frequency with which a physician in his practice may prescribe. Such an attempt would make the Court the arbiter of the practice of medicine. In *Strader* vs. *United States*, (C. C. A. 10, 1934) 72 F. (2) 589, the Court, in commenting upon a statement of the trial judge to the effect that the prescription to an addict is a violation of the law, and that the statute provided it may not be given merely for the purpose of relieving pain incident to addiction, said:

> We think the court incorrectly stated the law and unduly circumscribed the testimony. The statute does not prescribe the diseases for which morphin may be supplied. Regulation 85 issued under its provisions forbids the giving of a prescription to an addict or habitual user of narcotics, not in the course of professional treatment, but for the purpose of providing him with a sufficient quantity to keep him comfortable by maintaining his customary use. Neither the statute nor the regulation precludes a physician from giving an addict a moderate amount of drugs to relieve a condition incident to addiction, if the physician acts in good faith and in accord with fair medical standards.

I do not think that the case of DuVall against the United States (C. C. A. 9, 1936) 82 F. (2) 382, contains anything which detracts from that interpretation of the law. The Court there cites the Strader case. The Court there was not dealing with the question of the sufficiency of the testimony. The Court dealt merely with the instructions given by the trial judge. This is the instruction which the Court approved:

> If the prescriptions were issued in good faith and according to fair medical standards, in the curing of disease, and not merely to satisfy the cravings of the said persons for such drug, then they may be said to have been issued in the course of the defendant's professional practice only; but if the prescriptions were not issued in good faith, but were issued to enable such person to obtain morphin sulphate to satisfy his appetite and cravings for such drugs only, and not in the treatment of his patient, then the issuance of such prescriptions would not be in good faith nor in the course of the defendant's professional practice as a physician, and the sale and dispensing upon such prescriptions would not be lawful.

The Court then continues:

> Furthermore, although the court in its charge quoted the departmental regulation authorizing the supplying of morphin to aged or infirm addicts whose collapse would result from the withdrawal of the drug, provided he endorsed on the prescription that the patient is aged and infirm (giving age), or if he prefers he may endorse Exception 2, Article 85; the jury was nevertheless instructed to acquit notwithstanding the fact that the addict in the case at bar was only thirty-one years of age, if the prescription was made in good faith and in the course of the professional practice of the physician.

In the other case to which reference has been made, *Grigg* vs. *Bolton*, (C. C. A. 9, 1931) 53 F. (2) 158, the opinion was written by our colleague, Judge William P. James. There the question arose upon a writ of habeas corpus. It was a writ brought against the United States Marshal for the District of Montana claiming that the petitioner was being restrained under an indictment which charged him with no offense. We know the limited inquiry in such cases. On the face of the indictment, Judge James, writing for the Circuit, held that it stated an offense. He cited the Webb case and he cited the Jin Fuey Moy case. He did not cite the Linder case. I am satisfied that the decision was correct because the offense charged distinctly a sale and a conspiracy to violate the Act by unlawfully selling, bartering, exchanging and dispensing and possessing narcotic drugs to-wit, morphin sulphate, in violation of the law.

I am satisfied, therefore, that the Linder case and the cases which interpret it, lay down the rule definitely that the statute *does not say what* a physician may prescribe to an addict. Nor does it say the *quantity* which a physician *may* or *may not* prescribe. Nor does it regulate the *frequency* of prescription. Any attempt to so interpret the statute, by an administrative interpretation, whether that administrative interpretation be oral, in writing, or by an officer or by a regulation of the department, would be not only contrary to the law, but would make the law unconstitutional as it would be clearly a regulation of the practice of medicine.

The Courts have wisely held in determining what was or what was not the test of professional practice, that it should be determined in the light of expert testimony, in the light of the particular need of the particular occasion. In the case which followed the Linder case, *Boyd* vs. *United States* (1926) 271 U. S. 104, the Court limited the Linder case and criticized an instruction of the trial judge which would have limited the prescriptions to an addict to a single dose. The syllabus says:

> The mere fact that the quantity of morphin dispensed by a registered physician by a prescription to a morphin

addict without a written order, exceeds what would be required by the patient for a single dose, does not constitute a violation of the Anti-Narcotic Act.

The Court stated that the instructions of the trial judge in that case had language in it which went counter to the Linder case, but that certain other instructions cured the error of the others. The instructions were:

> I am requested to say to you, gentlemen, that in determining whether or not the defendant in prescribing morphin to his patients was honestly seeking to cure them of the morphin habit, while applying his curative remedies, it is not necessary for the jury to believe that defendant's treatment would cure the morphin habit, but it is sufficient if defendant honestly believed his remedy was a cure for this disease.
>
> I instruct you that if this is true, regardless of whether the course of treatment given by this defendant is a cure, the question is, was he honestly and in good faith in the course of his professional practice and in an effort to cure disease issuing these prescriptions.

The Court commented:

> With that addition the charge elicited no criticism or objection from the defendant, although there was full opportunity therefor. It evidently was regarded as consistent and satisfactory.

I have gone into this detailed discussion because Mr. Purdue, in the course of his argument, has stated it as his opinion that even if Dr. Anthony followed the school of thought which justified the prescription of narcotics under the circumstances and in the quantities prescribed, that, nevertheless, the prescription of large amounts to addicts would amount to a violation of the law, irrespective of his beliefs.

I cannot so interpret the meaning of the law. If I did, it would make the question of good faith not one to be determined upon the basis of the evidence, and expert testimony. We would have a situation where the Courts would arbitrarily say that, irrespective of the belief of the physician that he is effecting a cure or properly prescribing narcotics, the amount is excessive and is ipso facto a violation of the law.

Nor do I find in these cases anything to justify the statement of Mr. Purdue that the dispensing by physicians must be limited to an immediate need and that a physician cannot give to a patient a large prescription for self-administration under certain circumstances . . . warranted either by impossibility of hospitalizing the patient, or other conditions or by the desire to continue him at his work. . .

Nor can I find in these cases any statement of the law which says that where the physician is satisfied, from the patient's history and his own cursory examination, or where that patient is suffering from narcotism or other pathological conditions that require to be relieved medically by drugs, that he cannot rely upon the judgment of a duly established clinic maintained for a time by the City of Los Angeles, but must, because the Chief of Police and the narcotic officers have so requested, reexamine each individual case under the penalty of being prosecuted for violation of this act.

On the contrary, a study of these cases leads me to the conclusion that there is no dogmatic rule which the courts have laid down for the purpose of determining what is good or bad professional practice. What is good or bad professional practice must be established by the same rule by which the Courts determine whether malpractice exists in a certain case. In determining whether malpractice exists or not the Courts of California and the Courts of every state of the United States have laid down the rule, that a physician is not a guarantor of cure; that he is not a guarantor of even diagnosis; that he merely warrants by his employment that he will exercise ordinary care, the ordinary care of the physicians in his locality or in similar localities. Furthermore, the law of California is that what is good practice in a particular case is not to be determined by any abstract concept but by the opinion of experts whose testimony may be given in Court.

In a leading case on the subject in California, *Patterson* vs. *Marcus*, 205 Cal. (1928), at 533, the Supreme Court says:

> It has been held in this state that the implied contract on the part of the physician is that he possesses that reasonable degree of learning and skill possessed by others of his profession, and that he will exercise reasonable and ordinary care and skill in the application of that learning to accomplish the purpose for which he is employed. As to what is or is not the proper practice is uniformly a question for experts and can be established only by their testimony.

Reference is there made also to *Perkins* vs. *Trueblood*, (1919) 180 Cal. 437, where this is said:

> In McGraw vs. Kerr, 23 Colo. App. 163 (128 Pac. 873), it is said: "Negligence on the part of a physician consists in his doing something which he should not have done, or in omitting to do something which he should have done." Quoting further from the same case: "The authorities are practically uniform in holding that as to what is or is not proper practice in examination and treatment, or the usual practice and treatment, is a question for experts, and can be established only by their testimony."

So that, ultimately, the Court, in this case, is confronted with the duty of determining, from the evidence whether there is evidence in the record showing beyond a reasonable doubt that the treatment given to these addicts was not proper professional treatment under the circumstances, or, to put it conversely, whether the evidence establishes the fact, or raises a reasonable doubt that it is proper medical treatment.

I think Judge James, who tried this first case, correctly stated the law of the subject when he said, in his instructions to the jury:

> The law does not prohibit a physician from prescribing to an addict for self-administration, for the purpose of relieving conditions mental or physical which may be the product of addiction to the drug, or otherwise caused, such reasonable amounts, one dose or a number of doses of morphin, as fair medical standards recommend. In doing this the physician must act with the honest belief, based upon his medical knowledge, that the case reasonably requires such treatment. He is not to be held accountable for a mere error of judgment in such a case, or be held responsible to the law merely because results are not as favorable as he expected or anticipated. His responsibility is different, and he will be held accountable under the law, if he not using his best medical judgment in determining that the patient is in need of the treatment, issues prescriptions at the request of an addict merely to furnish such a supply of the drug as the addict may desire, in return for compensation received, or even without compensation. The last situation would be one that may be defined as an unlawful furnishing of narcotics and would be within the prohibitions of the law we are here applying.
>
> In determining whether a physician has acted in good faith in prescribing morphin for a patient, you are to consider what the accepted opinion of the medical profession is upon that point—if reputable physicians honestly hold to two opinions, some justifying the administration of morphin in the manner and in the quantities shown to have been administered by Doctor Anthony to the subjects named in the indictment, and others are honestly opposed to such opinion, and if the defendant held honestly to the opinion shown to be that of one group of reputable medical practitioners, and in the best of good faith acted accordingly, he would not be guilty. You have that question to decide and you are required to make up your judgment on the evidence submitted to you. Good faith on the part of the accused is an all-important element in the offenses charged—good faith according to fair or reasonable medical standards as understood by him. If you have a reasonable doubt as to what fair medical practice would require in the cases treated by the defendant, but find that the defendant believed he was acting according to good medical standards, he would be entitled to an acquittal. The purpose of the law, in making the exception as to practicing and registering physicians, is to allow the medical profession the right to prescribe such narcotic drugs as the necessary needs of their patients, in their honest judgment, require.

What the law punishes is *not bad judgment* in a physician, *but bad faith*. And the bad faith must appear. I agree with counsel for the Government that circumstances may arise, where, from the unexplained number of prescriptions, the unlimited amount, the relationship of the parties, an inference of bad faith might be drawn without any other evidence. But I do not think that the law compels such a conclusion as a finding—a dogmatic, irrevocable conclusion—to be drawn in all cases where the prescription is not limited to one dosage or several dosages. Where there is an explanation, the law relegates us to the position of having to determine, as the trier of facts, in the light of such testimony as has been presented by the experts in this case, and in the light of all the circumstances of the case and the testimony of the physician himself, whether or not there was good or bad faith.

The statement just made is broader than necessary because the presumption of innocence avails the defendant. And if the evidence is such as to raise in the mind of the trier of facts a reasonable doubt as to whether the practice followed by the physician was proper or improper, the judge, as the trier of facts, must, as would a jury under his instructions, under the doctrine of reasonable doubt, resolve that doubt in favor of good faith and acquit the defendant.

Now, if we analyze the cases treated by the defendant which have been brought before the Court, we divide them into two classes: Three cases which may be called "clinic cases" and the fourth a "non-clinic" case.

There is no need to go into a detailed discussion of the events which lead, first to the establishment and then the abandonment of the narcotic clinic in the City of Los Angeles. I am satisfied that everybody acted in good faith. These facts are undisputed: The authorities of the City of Los Angeles, at the behest of the Los Angeles Medical Society, confronted, as is every large city, with the narcotic problem—and particularly every large city which is within easy access of countries like Mexico, which are a great source of supply for drugs—were also confronted with the problems of a large number of addicts whose wants were being supplied by peddlers for remuneration. They approached the problem not dogmatically, but scientifically. And on the advice of medical authorities the health authorities of the City of Los Angeles established a clinic wherein those known addicts whose addiction had become pathological could, after being examined by physicians and certified, receive a quantity of the drug. It is also undisputed that thereafter (on May 11, 1934) a meeting was called and attended by representatives of various departments of the State, local and Federal governments interested in the matter. The meeting was called in the office of the Health Officer of the City of Los Angeles, Dr. George Parrish—the same officer who had continued the clinic which his predecessor, Doctor Powers, had established previously at the behest of the physicians. He testified that one physician was designated by his office to prescribe. Afterwards the clinic was taken over by the County General Hospital. He asked the defendant to come to the meeting because of the experience the defendant has had with the disease as a Federal physician appointed by the Government to look after the health of the Federal prisoners incarcerated in various jails. There is some disagreement as to what took place at the meeting. I think too much attention has been paid to the fact that Chief of Police James E. Davis of Los Angeles stated that under no circumstances could prescriptions continue without a reëxamination, and to the fact that Mr. Harry E. Smith, the United States Narcotic Agent for this District, made a similar statement. Ultimately, neither Chief Davis nor the Federal authorities can give an ultimatum to a physician as to the manner or treatment by him—as to a course of professional conduct—the violation of which would constitute a violation of the law.

The fact remains, however, that Doctor Parrish, the Health Officer of the City of Los Angeles, had asked Doctor Anthony to take over the prescribing for these addicts who had been certified by the clinic. Doctor Parrish testified that Doctor Anthony called him up, as the patients would be sent to him, told him that the police were giving him trouble, and that the Federal Narcotic Agents were creating difficulties, that he was "having too much grief and it was costing him too much in his medical practice" to continue this Good Samaritan act which he was doing at the request of his colleague. On one occasion he asked to be allowed to resign the position. The fact is also undisputed that during the seven weeks Doctor Anthony was actually paid by the City of Los Angeles the sum of $135 for taking over this clinic.

Now, we come to the men who were in the clinic—the three men—and we find, without going into any great detail, that each of them had been previously examined. Each of them had been certified to by the public physicians as suffering from chronic addiction which required treatment. We find in addition to that, and despite the fact that the number of cases made it impossible to examine them all at one time, the defendant made examinations of each of them.

I think the testimony of the addicts themselves is sufficient to show the defendant's good faith even if no one else had so testified. In fact, I am inclined to think that without the expert testimony of Doctor Orbison and Doctor Thienes, as to these three cases, at least, the defendant was entitled to a verdict of acquittal at the conclusion of the Government's testimony. But the fact that there was expert testimony to the effect that it was not proper medical practice, and there was no statement by the defendant except such as could be implied from the facts surrounding the prescriptions, that he acted in good faith, led me to deny the motion upon the ground that a prima facie case had been shown. Although I am inclined to the view that as to these three cases, even excluding the defendant's testimony and the testimony of the experts to the contrary, the Court could have concluded from the fact that the defendant was asked to take over the work and from the fact that he made such examination as he could, that he acted in good faith under the circumstances.

Let us look at the testimony of those three persons. Here is Jensen. He testified that he had been an addict for twelve years and had suffered from phlebitis, from backaches and had gone to Doctor Anthony. He described his pains to him and told him the nature of them and the names of the doctors to whom he had gone and who had given him narcotics. The defendant took both a urine test and a blood test. At first he didn't give him any prescription. The next time he not only prescribed the drug but he put some medicine on his back. He gave him morphin after the laboratory tests of the urinalysis and the blood analysis came back. He advised confinement, claiming that his addiction could be cured if he could stay in bed and have himself examined and treated. He told him that Dr. Edward Huntington Williams had examined him in 1935 and had said that he had syphilis and that a Doctor Smith had prescribed narcotics.

We come to Peter Mayers. He had been an addict for thirty-five years, and he claims to have a broken back. There is no dispute that he has a broken back and that some vertebrae had been removed. He had been getting from four to seven grains a day and was sent from the General Hospital. The defendant gave him a thorough examination; he examined him with a stethoscope and saw he was wearing a brace; he wanted him to come back for further x-rays and he gave him medicine for asthma. He testified that he had been examined by six physicians at the clinic before he was certified as an addict.

William Avery had been an addict for twenty-seven years. He had been examined at the clinic and headed the list of the names of the patients of the clinic that was given to the defendant. He made such examinations as he could make, but could not make a more thorough examination.

As to all these patients we have the statement of the defendant that, in his opinion, the prescription was proper under the circumstances. There is the testimony of Doctor Orbison and Doctor Thienes that, in their opinion, the amount prescribed was not necessary. Opposing this we have other testimony of Dr. George Parrish, as well as the testimony of Dr. Ross Moore, Dr. William Duffield, that it was a proper medical practice. I think Doctor Duffield testified to the fact that it was his opinion that ambulatory treatments were not correct. But these physicians and others testified that where drug addiction had become pathological the withdrawal of narcotics was not justifiable.

When we come to the Joseph Tint case we find that he was a "private," (i.e., a non-clinic) patient. Tint, according to his own testimony, stated that he had taken the drug for twenty-three years and that he suffered from arthritis. He had not been certified by the clinic, but had been examined by Doctors Carey and Williams. First, defendant declined to prescribe for him. Later he examined him and prescribed drugs and advised hospitalization. In all these cases the treatment was interrupted by the arrest of the addicts and later by the discontinuance of the treatment by the defendant.

I think that the evidence clearly shows not the case of a physician who looks for gain—in violation of that high ethical standard which should govern physicians—and, for profit, seeks to capitalize his knowledge by preying upon unfortunate addicts. I have nothing but contempt for that kind of physician. We here have a situation, as I see it, of a city medical department establishing a narcotic clinic and finding that it resulted in evil; and that the law enforcement authorities objected to it. closing it down and then this physician being asked—by the medical authorities to take over the work. There is no disputing the fact that Doctor Parrish asked the defendant to take over the work of the clinic and that he was paid by the city. It seems to me, Gentlemen, that under these circumstances to find that a physician who did so violated a law, merely because from the viewpoint of the law enforcement authorities, he was not so careful as he might have been with reëxaminations, and in issuing drugs to persons who, in their opinion, should be hospitalized—would do violence to the very spirit of the law; and to the very spirit of fairness which we must always read into the interpretation of any penal statute of the United States, as expressing that idea which is so prominent in the American people, the desire for fair play. It would mean that we might ask a person to do a thing and then say, "I am sorry, but you have committed an offense." That does not mean, of course, that a person might not be guilty of an offense although he followed the advice of the City medical authorities in such matters. I think he could be. It is not the law that a medical officer can give an absolution of criminal offenses any more than it is a law that the enforcement officers can, by placing their own interpretations on the law, create an offense which does not exist. But a physician is not punishable under this law, unless, under all the evidence in the case, he is shown to be guilty of bad faith, and has failed to follow accepted medical practice.

Can we say that a physician, who, at the behest of State authorities or City authorities took over the treatment of narcotic addicts, who supplemented the clinical record which he knew existed by his own examination, and administered drugs for a period of a few weeks, while he was treating each of these persons, is guilty of bad faith, and violates proper medical practices? The answer must be in the negative. Any other interpretation would make us dogmatic arbiters of the medical profession and would do harm to the anti-narcotic cause.

The conclusion I have expressed is made more imperative by the fact that we have expert medical testimony to the effect that the treatment which the defendant administered was proper under the circumstances and conformed, as one physician, Dr. Ross Moore, said, even to the high professional ideal of the Hippocrates oath. This oath makes it the duty of a physician to relieve suffering and to use his own judgment in so doing. He should not be punished when living up to it.

This applies to the three "clinic" cases. As to the "non-clinic" case—the case of Tint—I believe the evidence shows that the prescription was warranted. He went to the defendant because he understood from those who had attended the city clinic that it had been taken over by him. But whether we tie him to the clinic or not, the fact remains that he was and had been an addict over a long period of time; that he had been given narcotic prescriptions by others; that he was first refused by the defendant and that hospitalization was advised. The fact that Tint is cured now after long incarceration in a penitentiary especially equipped to deal with narcotism, should not be considered in determining whether the treatment was proper at the time. As to Mayers, Jensen and Avery, the evidence shows that the drug was withdrawn from them while they were in jail, by a physician who had no previous experience along these lines. But they have since returned to the habit, except as for such time as it was taken away from them during incarceration. Ultimately, however, even if the result was not what was expected, the question to determine is not whether *the judgment used was good* or bad, but whether the defendant *believed*, in all these cases, that the treatment he administered was proper by ordinary medical standards. The evidence supports the conclusion that he did so believe. Here, the evidence—exclusive of the defendant's own defense of his actions—warrants the conclusion that the practice was proper.

For the reasons indicated I find the defendant not guilty of any of the offenses with which he is charged in the four indictments. Exception to the Government.

Dated this 23rd day of June, 1936.

LEON R. YANKWICH,
U. S. District Judge.

THE LURE OF MEDICAL HISTORY†

MEDICAL CONDITIONS, PRACTICES, AND FOUNDATIONS IN THE CONTINENTAL COLONIES*

By HAROLD HANZLIK†
San Mateo, Calif.

PART I

INTRODUCTION.—According to Oliver Wendell Holmes, "The state of medicine is an index of the civilization of an age and country—one of the best, perhaps, by which it can be judged." This opinion is almost directly applicable to the situation existing in the early American colonies. The struggle of medicine, just like that of other vital parts of the American colonies, had to overcome superstitions, a partnership with priesthood, and false philosophies. All these obstacles had to be conquered, dissolved, or eliminated before the means which nature and art have put in the hands of physicians could be brought to practical use. Nothing brings to light the superstition of an age more than the treatment and interpretation of disease of those early times. With these thoughts in mind, it is the object of this paper to discuss the prevailing, and sometimes appalling, conditions and practices among the small group of settlements known as the Continental Colonies of America, and the resultant developments for medicine.

The period to be discussed covers a span of some 180 years in this country, that is, between the years 1620 and 1800. It was the period when in Europe great universities were being founded and important medical discoveries made. The University of Edinburgh had been chartered, and it was here that the leading colonial physicians were trained. Human dissection was being revived, the University of Edinburgh having built its first anatomical theater in 1697. Descartes had published the first treatise on physiology. The Reverend Stephen Hales had, for the first time, measured the blood pressure in a horse in 1726. He also produced dropsy by injecting water into the veins. The first clinics for poor patients were organized in Prague in 1745. Lavoisier had discovered oxygen in 1775, and shown its importance in breathing. Among the most important of all medical developments was the discovery of the circulation of the blood by that immortal physician, William Harvey, in 1628. Europe at that time was no doubt a long jump ahead of the American colonists, who admittedly labored under great handicaps and disadvantages. However, it will be presently shown that, despite all obstacles, they were not found wanting, and that they and theirs laid the foundations of lasting and permanent benefits to medicine and to humanity throughout the world. They caught up with and passed the Europeans.

IN THE DAYS OF THE PILGRIM FATHERS

Let us turn to the Pilgrim Fathers, and consider first the state of their early settlement. It seems that these weary travelers were beseiged by many diseases, some of a fatal nature. Many medical historians are inclined to believe that the climate disagreed with these travel-worn souls. In all probability this was true, since the older physicians wrote considerably about the prevalence of the common cold, pleurisy, and pneumonia, which, no doubt, were caused by the extremes of climate in the eastern states. The colonists were plagued with one disease in particular, namely, scurvy. They had neglected to bring along the fruits and products which contain the necessary vitamins for the prevention of scurvy. Consequently, many of them died before reaching land, and some died even after they had landed. Those who landed at Cape Cod, after the long journey from England, were a forlorn lot of gaunt and hungry creatures longing for fresh food. They found "great mussels, and very fat and full of sea pearl" (Packard). Both passengers and sailors indulged liberally in this dangerous delicacy, and soon these way-worn travelers were treated to a gastric remembrance of the "heaving billows," now gratefully behind them. The food was not only unpalatable, but it made them generally ill. Nevertheless, the Pilgrim Fathers had to subsist on this food, with the result that the scurvy increased alarmingly. Had it not been for the discovery of some wild berries and grapes they might have all perished. As it was, many died: in December six died; in January, eight; in February, seventeen; and in March, thirteen. With the coming of spring the mortality rapidly diminished. The little community, depleted of able-bodied men, and with many of the living crippled and sick, nevertheless took heart and started building. They had to commence from the ground up; almost everything seemed lacking, even good health, without which there can be nothing.

Undoubtedly one of the most pressing needs of these early settlers was medical attention and sanitation. In Savage's "Genealogical Dictionary of First Settlers Before 1692 and Their Descendants," there are scattered throughout the names of 134 practitioners of the healing art. Of these, twelve professed, but probably many more practiced. surgery, since there were also barber-surgeons. It is interesting to note that the practice of medicine, or "physic," was only a sideline, or avocation, with these individuals. Their main business or work was something else. For instance, one man was a schoolmaster and poet; one kept a tavern and practiced "physic." One was a butcher, but called himself a "surgeon," and, doubtless, the connection with his real profession was not far remote. One female practitioner "employed by her own sex—Ann Moore—was one of the more noted midwives" (Mumford). It was a motley lot of talent, much of it crude and amateurish, and a danger to the little community.

MEDICAL PRACTICES AND PRACTITIONERS DURING THE COLONIAL PERIOD

A student of history might inquire into the doctrines, theories, or practices of healing which these colonists brought with them. There were two principal schools of thought in the Old World at this time, and to one of these the colonists did not subscribe. This one was the old philosophy of Galen based on the theory that the body was made up of four main elements, namely, fire, air, water, and earth, which possessed the qualities hot, dry, moist, and cold. In order to be in perfect health, a man had to keep these qualities in equal proportion to each other. Diseases, which had as their cause an excess of heat, were quieted by cooling remedies; those originating with an excess of cold, by heating remedies, and so on. The leading principle of the Galenists was this: "Disease is to be treated by anything that is proved to cure it" (Holmes). The cures employed by the Galenists consisted chiefly of diets and vegetable remedies, with the use of a lancet or other devices of similar nature. If the Galenists lived today, they would probably be called "herb doctors." These practices were eventually discredited, due to the nauseating concoctions, and the absurdly complicated mixtures, which sometimes were worse than the disease.

The other, or chemical, school of healing was a much simpler idea, and depended chiefly on the use of mineral remedies, such as sulphur, mercury, antimony, and arsenic, with a secret use of opium at times. This school did much to replace the old, repulsive herbal concoctions with more agreeable and effective remedies. It was this school that the New England fathers followed. The prescriptions of their physicians contained a few potent drugs. In one of the manuscripts sent to Governor Winthrop, in 1643, by a certain Doctor Stafford, the following prescription was included: " . . . for yellow Jaundise—Boyle a quart of sweet milke, dissolve therein as much bag-salt, or fine Salpeter, as shall make it brackish in taste; and putting Saffron in a fine linen clout, rubb it into ye Milke, untill ye Milke be very yellow; and give it ye patient to drinke" (Packard). This example is cited in order to show that the remedies prescribed for the colonists consisted mostly of simple chemical and household ingredients.

The most common practice, however, among the colonial physicians was blood-letting. For every disease or injury the physician would "let blood," sometimes to a point of near exhaustion. There is a written account of this practice by

Doctor Fuller, who was one of the earlier colonists and also one of the best physicians, to Governor William Bradford, dated June, 1630, in which he indicates its scope during one of the many malarial epidemics. He states, "I have been to Dorchester, and let some twenty of these people blood." For once this blood-letting might have helped the patient, although weak and exhausted, because malaria is a disease of the blood, and by removing blood the patient was freed of the microörganisms causing the illness. Nevertheless, a great many of the colonists succumbed to this disease, and even the physicians themselves were not spared.

It is interesting to note that one of these colonial physicians was more successful in teaching his colleagues and influencing public opinion than he was in the practice of his art. He was Dr. Giles Firmin, who practiced "physic" (medicine) in the colonies for a time, but it seems that business was none too good. For, in a letter to Governor Winthrop, he writes that he will study divinity because "physick is but a meene helpe." Be that as it may, Doctor Firmin's lectures and dissections in anatomy were the first real scientific medical teaching in the New World. While many of the colonists regarded this as nonpuritanical practice, the New Englanders were broad-minded enough to allow the teaching of anatomy. The Puritans were, nevertheless, severe in dealing with quackery. For, in 1631, one Nicholas Knopp was fined fifty pounds and sentenced to be whipped for "taking upon him to cure the scurvy by a water of noe worth or value, which he sold at a very deare rate." If such a rule were enforced today, there would be quite a number of sore backs and not a few of their owners with empty purses. Such unscrupulous men as these, the decent colonial doctors were forced to combat continuously. As a result there were formed organizations of medical practitioners which eventually developed into the medical societies of Philadelphia, Massachusetts, New York, and Maryland. An interesting purpose of the constitution of one of these organizations was that the community might be benefited by such a union of doctors. Accordingly, a meeting was held in 1765 by the doctors of the Philadelphia Medical Society to "consider and report matters relative to physic." The society considered several papers upon subjects which were of fundamental importance to medical practice at that time. Some of these were: "Dissertation on Causes, Nature and Treatment of Apoplexy," "On Consumption," "An Essay on Virtues and Uses of Several Substances in Medicine, that are The Native Growth in America" (Norris). The last paper dealt with remedies prescribed for such plagues as smallpox, insanity, broken bones, fevers, and king's evil. The remedies were such humble and innocuous herbs and vegetables as St. John's wort, maiden hair, parsley, and elder. All these were considered curatives, and most of the physicians prescribed them religiously. However, these were not the only remedies in use; there were also mechanical devices. For instance, as early as 1634, a Dr. John Clark mentions the use of the trephine as a surgical instrument for cutting round pieces of bone out of broken skulls. While trephining is a very old operation, and is said to have been practiced by some Indians, it seems that colonial physicians were not overlooking anything which added to their skill, although they must have made this operation without anesthesia, which came later.

From what has been said, the New England physician of Colonial times may be regarded as a cross between an herbalist, a pharmacist, and a surgeon. This gives a fair idea of a combination of superstition and crude empiricism inflicted on a patient who fell into the hands of an intelligent and somewhat educated physician of the middle seventeenth century. Governor Winthrop of New England himself was a fair example of a seventeenth century physician, although not a trained medical man. His great remedy was nitre, which he ordered in doses of 20 to 30 grains for adults, and of 3 grains for infants. Measles, colic, sciatica, headache, and other ailments were all treated with nitre, and many patients were undoubtedly improved. For nitre was a pretty safe medicine in moderate doses for patients naturally recovering anyway, and one not likely to keep the good governor awake at nights. He also gave sulphur and antimony, along with the very harmless "powder of coral," less frequently a dose of powdered amber, and sometimes, as a last resort, a dose of cowhage, which caused a fearful upset of the stomach and intestines.

CLINICAL NOTES AND CASE REPORTS

RELAPSING FEVER*

By R. C. Atkinson, M. D.
Colfax

REPORT OF CASE

“Dr. R. C. Atkinson then delivered an address to the Placer County Medical Society, taking up the subject of relapsing fever, and reported a case of this disease which occurred recently, in his practice, in a man of fifty-eight years who had been visiting in the Lake Tahoe area and apparently had received the infection while there. In his paper, Dr. Atkinson discussed the epidemiology of the disease and its importance to physicians in California because of the large number of people using the parks and national forests in which the disease is endemic among the squirrels and chipmunks. The first cases reported in California were announced in 1922, by Dr. LeRoy Briggs, of San Francisco, and there is an excellent article on this subject by him in California and Western Medicine, May, 1935. Since Dr. Briggs published a report of these two cases from Polaris on Lake Tahoe, eighty-six others up to January 1, 1935, had been reported to the State Department of Public Health. A large proportion of these cases occurred from two endemic foci; one in the region of Big Bear Lake in San Bernardino County, and one in the Lake Tahoe region in eastern Placer and El Dorado counties. The disease is most common in the months of June, July and August. Males are affected twice as frequently as females, due probably to their greater use of the out-of-doors. The incubation period averages seven days, and is usually under twelve days. The onset is abrupt, with the fever reaching its height within twenty-four hours and continuing for from three to seven days. The patient complains of chills, malaise, generalized aches and pains, sweats and headaches. Aside from a moderate enlargement of the liver and of jaundice, in about one-fifth of the cases, there are no characteristic physical findings. With the exception of a slight anemia, the blood count is usually normal, but may show a polymorphonuclear leucocytosis at the height of the paroxysm. Blood smears taken at the time of paroxysm, either fresh or stained with Wright's stain, will show the organism, which is a treponema. Smears taken during the afebrile period are less apt to show the organisms, but citrated blood in normal saline taken from the patient is infectious to mice, and the organisms may be recovered after a few days, if an injection is made into the peritoneal cavity of the mouse, even though the blood is taken several days after the paroxysm. The febrile period terminates after three to seven days, and is followed by an afebrile period of three to seven days, during which time the patient feels well and may be up and around. This, in untreated cases, is followed by recurrence of the fever and symptoms, lasting, on an average, for seven days—the attacks tending to become less severe as time goes on. A single injection of .3 grams to .45 grams of neoarsphenamin intravenously terminates the disease at once in 80 per cent of the cases. Subsequent injections of one or two doses of .3 to .45 grams are usually advised. Dr. Atkinson demonstrated the organisms of relapsing fever under the microscope with smears taken from his patient.

“Because of the increasing prevalence of relapsing fever in the Lake Tahoe region, Dr. Atkinson's paper was very timely.”

Box 327, Colfax.

HEPATIC CIRRHOSIS WITH ENCAPSULATED PERITONITIS*

REPORT OF CASE

By C. A. Noble, Jr., M.D.
I. H. Perry, M.D.
and
H. H. Marquis, M.D.
San Francisco

Purulent peritonitis as a complication of cirrhosis of the liver is an uncommon occurrence. From a review of the literature, we believe that such a case is of sufficient infrequence and general interest to warrant a brief report.

REPORT OF CASE

The patient was a mulatto male, aged 64, whose illness began about six months before entry, with some increase in the size of his abdomen, following a short period of vague digestive disturbances. He was an habitual user of alcohol for a considerable number of years. The remainder of his history was essentially negative.

On physical examination, his abdomen was somewhat distended with fluid. A non-tender, firm liver-edge was palpable above five centimeters below the costal margin. The spleen was not felt. There was no evidence of jaundice. There were distended veins over the lower chest and abdomen, indicating increased collateral circulation. He had an unmistakable hepatic facies. Otherwise, the physical examination and the laboratory studies, including the Wassermann reaction, were essentially negative.

A diagnosis of portal cirrhosis was made; and palliative treatment was instituted, with the use of diuretics.

Three and one-half months following examination, paracentesis was first performed with the removal of 2,400 cubic centimeters of chyliform fluid, containing eleven lymphocytes per cubic millimeter. After a five weeks' interval, the patient was again tapped and 8,600 cubic centimeters of straw-colored, slightly cloudy but not chyliform, fluid were withdrawn, containing 628 leukocytes per cubic millimeter, 58 per cent of which were polymorphonuclear cells. At a third paracentesis, two weeks later, 6,000 cubic centimeters of fluid, containing 6,040 cells with 89 per cent polymorphonuclear leukocytes, were obtained. Paracentesis was attempted three weeks following this, but in spite of a markedly distended abdomen, no fluid was obtained. Two weeks after this, another puncture yielded 8,000 cubic centimeters of thick, foul-smelling, purulent material, a smear of which showed mostly polymorphonuclear leukocytes and bacteria. By culture, organisms of the colon group were grown, including B. coli, B. paracoli, and enterococcus alpha. Ten days later, 1,600 cubic centimeters of a similar fluid were withdrawn. During the five days following this paracentesis the patient's condition became progressively worse, and on the fifth day exitus occurred.

---

* From the Departments of Medicine and Pathology, University of California Medical School, in their services at the San Francisco City and County Hospital and the Laguna Honda Home.

During the entire course of his illness the patient had only slight fever. His pulse rate was normal, and his appearance gave no evidence of the severity of his condition as indicated by the aspirated fluid. His abdomen was never tender nor rigid; and at no time did he complain of nausea, vomiting, or diarrhea. The leukocytes in the blood stream at the time of the first tap, in which purulent material was obtained, numbered 13,600, with 64 per cent polymorphonuclear leukocytes; at the time of his last tap, ten days later, the number of leukocytes had risen to 60,000, with 85 per cent polymorphonuclear cells.

At postmortem examination, a large, thick-walled abscess was found; this contained about two gallons of greenish-grey, foul-smelling pus.† The abscess extended from the upper part of the pelvis, where it was adherent to the bladder, nearly up to the umbilicus in the midline, and about 10 centimeters higher in each flank. The anterior boundary of the abscess was the parietal peritoneum of the anterior abdominal wall; posteriorly it was enclosed by matted and distorted intestines. In the midline, near the upper part of the abscess, its anterior and posterior walls were densely adherent at one point. Leading anteriorly from this point was a closed fibrous and necrotic tract which extended to the skin of the linea alba. The size and position of the tract suggested that it might represent the site of an old paracentesis. Posterior to these adhesions of the abscess walls, the intestines were more densely attached to the abscess than elsewhere. The abscess wall was about one-half centimeter thick. Its inner surface was necrotic, and flecked with fibrinopurulent plaques (Fig. 1). The thickness and density of the wall indicated a long-standing process. The intestines, which were densely adherent over the posterior surface of the cavity of the abscess and to each other, were pushed backward and upward. There were no fistulous tracts between the abscess and the intestines. Between adherent coils of the intestines were small pockets of clear, amber fluid, and one small cavity containing chyliform fluid. No cysts were found in the mesentery nor any other lesions except the adhesions described above.

The appendix could not be located. A ruptured appendix did not, however, seem a probable source of the abdominal abscess, as coils of intestine lay between the cecum and the abscess cavity.

The gall-bladder, although involved in adhesions, was essentially normal.

The liver, both grossly and microscopically, showed the characteristic picture of portal cirrhosis, with fibrous tissue radiating from the portal spaces and replacing the normal parenchyma. The pancreas was normal. There was no indication that it bore any relation to the abscess.

The lungs showed the presence of a terminal bronchopneumonia, which appeared to be the immediate cause of death.

COMMENT

Peritonitis in patients with cirrhosis, as well as in those without this diease, might arise by either endogenous or exogenous routes. Endogenous peritonitis may result from: (1) direct extension from infection within adjacent viscera, either by their rupture or by penetration of their walls by the offending organisms; (2) infection transferred by lymphogenous paths; and (3) infection transferred by hematogenous paths. Exogenous peritonitis may result from: (1) direct infection of the peritoneal surface, such as may occur at operation; (2) trauma, as may occur with bullet wounds; or (3) paracentesis. That the last mentioned may be an etiologic factor in peritonitis, is shown by Pflaum,[1] who specified paracentesis as the cause of 7 out of 741 consecutive deaths from peritonitis.

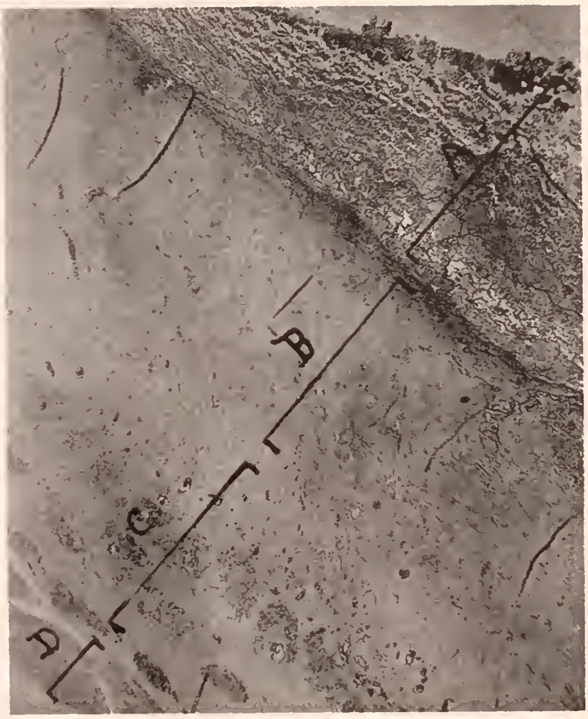

Fig. 1.—Wall of abscess. Magnification, seventy-five times. *A*, interior of abscess, fibrinopurulent exudate; *B*, fibrous wall; *C*, granulation tissue; *D*, muscularis of intestine.

That peritonitis should very frequently occur in patients with cirrhosis would seem reasonable, since this disease damages extensively an abdominal organ connected with the bodily defense mechanisms. A wide variety of pathogenic organisms are found. Experimentally, Fiessinger [2] and his coworkers have found that in animals with phosphorus or chloroform poisoning, resistance to pneumococcus and streptococcus infections was less than in normal controls. Benians,[3] working with rabbits, found that animals injected intraperitoneally with gum would succumb to peritonitis following intravenous or intraperitoneal dosage of B. coli, which normal control animals could withstand.

The rarity of occurrence of peritonitis in patients with cirrhosis of the liver is still subject to difference of opinion. Soubourin,[4] as early as 1881, noted tuberculous peritonitis as a frequent complication of hepatic cirrhosis. Lemierre and Delbriel,[5] on the other hand, deny that tuberculous peritonitis is common in patients with cirrhosis, using as an argument the fact that rapidly progressive tuberculosis in alcoholics usually spares the peritoneum. Dumitresco and Olinesco [6] believe that secondary infection of ascitic fluid is a rare complication. Rolleston[7] states that all patients whose hepatic disease outlasts two paracenteses, have their ascites on the basis of low-grade chronic peritonitis. Hawkins and Fletcher,[8] Scrimger,[9] and Rendu,[10] all feel that terminal peritonitis is a common accompaniment of cirrhosis of the liver, as it is, likewise, of cardiac insufficiency and nephritis.

---

† A guinea-pig inoculated intraperitoneally with this material did not develop tuberculosis.

[6] Dumitresco-Mante, and Olinesco, R.: Ibid, 50:214, 1926.

Due to the absence from the literature of carefully summarized data, including differential and total blood counts, report of cultures and records of subsequent autopsy findings, the question of the frequency of association of peritonitis with hepatic cirrhosis must remain unsettled. In a series of 264 cases of cirrhosis of the liver at the University of California Hospital, only twelve patients by paracentesis showed fluid with a differential count of ten or more per cent polymorphonuclear leukocytes. In only one patient was the white count of this fluid as high as 4,000 per cubic millimeter. This was obviously not such purulent material as was encountered in the patient presented in this paper.

Lemierre and Delbriel[5] report two patients with cirrhosis, in both of whom abdominal paracentesis was followed by a sharp rise in temperature, a rise in the ascitic white blood cell count, and a positive ascitic culture. One of these patients lived for at least two months with a normal ascitic fluid shown by subsequent punctures. Finally he developed symptoms and died of a colon bacillus-peritonitis three weeks after the last tap. These authors feel that many patients who have never been tapped develop peritonitis; and that in many cases the offending organism is one such as the pneumococcus, which is neither a contaminant nor a usual inhabitant of the colon. The fact that purulent peritonitis in cirrhotics is rarely due to puncture, should be of some solace to physicians in whose patients this complication develops.

Pitsoris[11] reports three patients with cirrhosis in the early stages, without ascites, in whom acute abdominal symptoms suddenly developed, with death from purulent peritonitis. In one of these patients, mesenteric thrombosis may have been the cause; in another, otitis media with septicemia; but in the third no source for an enterococcus peritonitis was found.

In the patient presented in this paper, the source of the peritonitis might be questioned. Autopsy showed no rupture of an adjacent viscus such as the gall-bladder, nor interference with the circulation of the bowel. The appendix was not found, nor had it been previously removed. If the infection resulted from an appendicitis, one would have expected more pericecal adhesions, and the bulk of the infection would have been on the right; also, normal loops of intestine separated the abscess from the cecum. Moreover, the organisms found on culture were frequent inhabitants of the intestinal tract; and the sinus from the abdominal wall appeared to lead from one of the paracentesis wounds to a loop of bowel. Puncture of an unattached loop of bowel is difficult. Perhaps a transient previous peritonitis had occurred, as has been reported by Lemierre and Delbriel.[5] It is our assumption that in some manner the bowel had become partly adherent to the anterior peritoneal wall, and that it had been penetrated during paracentesis. In this way a peritonitis resulted, which was walled off by previous adhesions or by natural resistance. Gradually this increased in size to form the large "pus pocket" found at postmortem examination.

In this patient the feature of particular interest was the enormous thickness of the pyogenic membrane, suggesting an infection of at least several months' duration. The finding of three cavities within the peritoneum, containing separate fluids so that each could be tapped independently of the others—one yielding pus; the second, normal ascitic fluid; and the third, chylous fluid—must be an almost unique experience.

Rendu[10] calls attention to the absence of pain and to low fever in peritonitis associated with cirrhosis, and suggests the symptoms of diarrhea, nausea, vomiting, and hiccoughs, as aids to diagnosis. The striking lack of toxicity in our patient is to be emphasized, and the presence of little fever, a slow pulse and a low white blood cell count, although from 6 to 8 liters of pure pus must have been contained in the peritoneal cavity for days and probably even for weeks before death.

SUMMARY

1. The case of a 64-year-old mulatto male, with cirrhosis of the liver and symptomless encapsulated peritoneal abscess yielding eight quarts of pus, is herewith presented.
2. The literature on the association of peritonitis and cirrhosis is briefly summarized.
3. Such a survey of the literature reveals the lack of data correlating, by repeated paracenteses, cultural and cellular studies.
4. It is suggested that, in view of the lack of symptoms in cases reported, peritonitis of a low-grade type may be a frequent concomitant to cirrhosis of the liver; but that such a picture as the one presented must be very rare.

MERALGIA PARESTHETICA

By Maxwell Thebaut, M.D.
Oakland

MERALGIA paresthetica is a well defined, but infrequently recognized affection of the lateral femoral cutaneous nerve. It was first described independently by Roth[1] and Bernhardt[2] in 1895. It is characterized by paresthesia of the outer side of the thigh, is usually unilateral, but may be bilateral. The disturbance of sensation may extend from mild numbness to intractable pain. There may also be tingling, itching, and burning.

---

[1] Roth: Meralgia Paresthetica, Berlin, S. Karger, 1895. Obtained from reference 4.

[2] Bernhardt: Ueber isoliert Gibiete des Nervus cutaneus femoris externus vorkommende paraesthesien, Neurol. Centralbl., p. 242, 1895. Obtained from reference 4

Some writers regard the disease as comparatively rare, but it is the author's opinion that the wide range of severity seen in different cases is responsible for this. Patients are frequently indifferent to symptoms that do not cause them actual distress, and it is probable that in some of the milder cases they do not consult a physician. Moreover, the entity may not always be in the mind of the examiner.

Definition. — Stedman defines meralgia paresthetica as "tingling, formication, itching, and other forms of paresthesia in the outer side of the lower part of the thigh in the area of distribution of the external cutaneous branch of the femoral nerve; there may be pain, but the skin is usually hypesthetic to touch."

Etiology.—Many theories have been advanced to account for this symptom complex. Rosenheck[3] believes osteo-arthritic changes in the spinal vertebrae are responsible. Stookey[4] believes it arises as a result of mechanical causes due to angulation of the nerve as it emerges from the pelvis; that a low-grade trauma is set up due to the nerve not being long enough to avoid excessive angulation and tension at this point. (For a more detailed discussion of the etiologic factors offered, the reader is referred to the article by Bergsma.[5])

Pathology. — To my knowledge no gross or histologic changes have been demonstrated.

Age and Sex.—Most writers are agreed that the disease occurs most often in the middle decades, and that men are afflicted somewhat more frequently than women.

Symptoms.—The symptoms are confined to the area on the outer side of the thigh that is supplied by the lateral femoral cutaneous nerve. They consist chiefly in numbness, pain, burning, pricking or itching of the skin. On examination, anesthesia or hyperesthesia may be noted in some patients. There may be a lessened appreciation of temperature changes. The pain may be worse on standing and may be severe. At times the presence of clothing will be uncomfortable. In contrast to these patients with pain and burning are those to whom I would call attention, who do not find themselves particularly distressed. These may have only a sensation of numbness and occasionally a slight tingling in the affected area, and unless some unrelated circumstance leads them to their physician they probably would not seek his advice. One of the cases reported herewith comes in this group.

Treatment.—In severe cases specific measures have included sectioning of the lateral femoral cutaneous nerve as it emerges from the pelvis, with avulsion of the distal portion; or sectioning the nerve in the same location, but leaving the distal portion *in situ.*

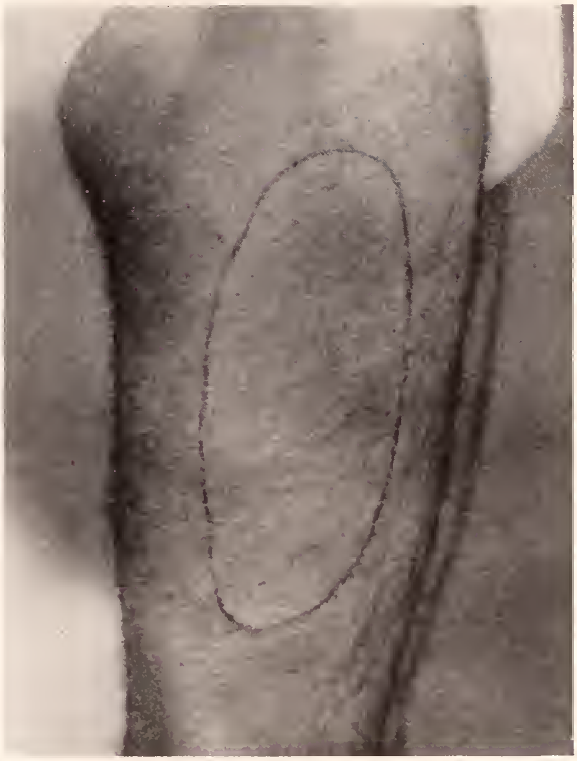

Fig. 1.—Area of involvement of meralgia paresthetica in Case 3.

Recent researches, called to our attention by Reichert,[6] have shown that peripheral nerves contain, in addition to somatic fibers, sympathetic fibers carrying vasomotor, pilomotor, and sudomotor efferent fibers, and afferent sympathetic fibers carrying pain impulses. If this be true, blocking of the sympathetic fibers would appear to be a more rational mode of treatment, and Reichert's reported cases bear this out. He found that paravertebral block with alcohol of the second and third sympathetic ganglia gave immediate relief; one case required reinjection due to incomplete block.

REPORT OF CASES

Case 1.—Miss A. G., a 21-year-old stenographer, complained of numbness and tingling of the outer portion of the right thigh. This area presented a normal appearance, but did not respond to painful stimuli or light touch. Temperature response was normal. Two months later the area seemed about the same in extent, but the anesthesia and tingling were definitely lessened in degree. Four months later the symptoms had completely disappeared, and have not recurred during a period of two and one-half years.

⁂

Case 2.—Mrs. J. D., a 25-year-old housewife, during the course of an examination for pregnancy mentioned that for two days previous to her visit she had noticed an area of numbness of the skin of the outer aspect of the left thigh. An area was found that did not perceive painful stimuli or light touch. There were no other abnormal findings. During the course of the ensuing two months the symptoms and physical abnormalities completely disappeared.

Case 3.—Mr. T. M., a 22-year-old college student, complained of an area on the outer side of the right thigh (Figure 1) that was numb and tingled, and at times was slightly painful. An area was discovered about the size of one's hand where light touch and painful stimuli were not perceived. Symptoms gradually disappeared in the course of four or five months, and there has been no recurrence in five years.

None of these cases received treatment.

SUMMARY

1. Meralgia paresthetica is defined and its etiology, pathology, and treatment discussed.
2. The likelihood that the disease is not uncommon is suggested.
3. Histories of three cases are presented.

1904 Franklin Street.

PHLEBITIS: ITS TREATMENT

By Norman J. Kilbourne, M.D.
Los Angeles

In view of the frequent incidence of phlebitis, and the fact that six per cent of postoperative deaths are due to its sequelae, sepsis and pulmonary embolism, it is fitting that more attention be directed to its treatment.

Phlebitis, when not chemical, is caused by three factors: infection, plus either stasis or trauma, or both. The probabilities are strong that so-called traumatic thrombosis, over which there is now so much medico-legal discussion before the Industrial Accident Commission, occurs with infection as a contributing factor. The absence of a positive blood culture proves nothing. What is conclusive is the work of French surgeons, who cut down on the thrombus in "traumatic" thrombosis, and who repeatedly obtained heavy cultures of streptococcus and staphylococcus from the thrombus.[1]

Preventive Treatment. — Phlebitis, after operation, may be prevented by avoiding stasis in the veins. This requires that in postoperative care the patient must be taught to move his legs at least five times a day and take frequent deep breaths, beginning as soon as he comes out from under the anesthetic. This provision should be continued until he is out of bed. The leg movements propel the venous blood, and the deep-breathing movements of the thorax aspirate it.

Severe phlebitis, after injection of varicose veins, is due to infection. This infection may be prevented by using, in very large veins which are most susceptible to phlebitis, only the strongly bactericidal solution of quinin urethane.[2] This quinin is adsorbed into the endothelial cells.

ACUTE PHLEBITIS

Curative Treatment of Acute Phlebitis demands compression of the superficial veins with an elastic, linen-mesh bandage. If the phlebitis extends above the knee, it will be necessary to use, from the knee up, an adhesive elastic bandage, such as the elastoplast bandage, for the ordinary linen-mesh bandage will not stay on above the knee. The compression of these superficial veins is the outstanding factor in treatment. The compression bandage should be carried continuously up above the level of the phlebitis, for there is a strong opinion, which originated with the late Sicard of Paris, that an embolus is thus less likely to be liberated.

The common treatment by ice packs in acute phlebitis is dangerous: since the tissues suffer both from infection and venous stasis, and the lymphatic obstruction always associated with phlebitis, they have low resistance to the ice. One such patient who came to the author had a gangrene, due to the ice, extending from the ankle to the upper thigh and deep through the skin, and subcutaneous fat far down into the sloughing muscles. She was moribund. (Treatment of this ice-burn with tannic acid saved both the leg and the patient's life.)

Another still more common error is prolonged immobilization of the phlebitis patient in bed. This customary treatment is based on the ordinarily sound principle of treating infection with local rest to the part. It, however, overlooks blood stasis as a fundamental factor in causing phlebitis: the bacteria thrive on stagnant, degenerating blood elements. The modern procedure gets the patient out of bed early, and the results have justified the change. It takes some judgment to know how soon to get the patient out of bed. If this procedure is followed with good judgment, the danger of embolism is not as great as the danger of embolism from allowing venous stasis to continue by long bed rest. The common practice of keeping phlebitis patients in bed for seven weeks is strongly to be condemned.

CHRONIC PHLEBITIS

Treatment of chronic phlebitis requires bandage treatment as above. A few patients are not cured by the bandaging, and after a period of time, such as two or three months, they should be treated by high voltage x-ray, as described by Halban.[2] Roentgen treatment is of great value in old, chronic phlebitis, especially chronic phlebitis with edema. Roentgen treatment should never be used until the phlebitis has been chronic for a long time.

It is sometimes impossible to draw a sharp line between chronic phlebitis and Buerger's disease. In fact, phlebitis migrans probably is Buerger's disease. Too much emphasis cannot be laid on the prohibition of smoking in these cases.

Watch for the case of chronic phlebitis which shows no enlargement of the leg on the affected side. Many of these patients are no longer suffering from chronic phlebitis. Their misery is due to pes planus.

2007 Wilshire Boulevard, Los Angeles.

An Arab proverb runs as follows:
"The world is supported by four columns:
The justice of the great
The prayer of the righteous
The bravery of the valiant, and
The science of the physician."

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

HAMMER-TOE

ETIOLOGY

Leonard W. Ely, M. D. (Stanford Hospital, San Francisco).—At first sight this seems a very simple question, but on further thought the question is not as simple as it seems. As usual, in foot deformities the shoe is blamed; and as the second toe is the one most often afflicted, the pushing of it over by the great toe is supposed to be responsible, but the great toe could just as well push over the other toes. Further, people wear about the same kind of shoes, but not one in a hundred, perhaps, is afflicted with this deformity. Again, even when the toes are deformed by tight shoes, they are not deformed in the peculiar manner of hammer-toe. And still, the peculiar stiff contracture of this deformity is difficult to explain on this hypothesis. Indeed, even when treatment is started early in life, the deformity is hard to correct.

Hammer-toe often begins in early life and, in spite of treatment, slowly progresses until it reaches its complete stage. It usually runs in families: either a parent or a grandparent of the patient will be found to have it; and of a number of children in the same family only one, as a rule, will have it. We are forced to the conclusion, therefore, that hammer-toe is a congenital deformity. This will account for its peculiar form, for its occurrence, and for its slow and steady increase until it reaches its full degree. It explains practically everything, in fact, about the causation of hammer-toe.

* * *

SYMPTOMS AND PROGNOSIS

Samuel S. Mathews, M. D. (1913 Wilshire Boulevard, Los Angeles).—The symptoms of this deformity are due entirely to the pressure of the shoe on the top of the flexed toe, and a downward thrust of the terminal phalanx onto the sole, thus resulting in painful calluses. The patient oftentimes has to resort to a very soft shoe or slipper, to be able to walk with any appreciable amount of comfort, and in desperation he is willing to have the toe removed, this being a request when frequently seeking medical aid for the first time. Most commonly affected is the second toe, in which the first phalanx is dorsiflexed and the second plantar flexed, while the third may be extended with the toe held fixed in this position. There is a constant pressure being exerted by the top of the shoe on the apex of the deformity and the resultant callus formation on the terminal phalanx. This condition must not be confused with the claw-like toes met with in various forms of talipes, in which all the toes are affected. These symptoms are much more severe and also much more difficult to treat, from a surgical standpoint. It is quite common to find hammer-toe associated with halux valgus. The large toe rides over the second one and maintains the second and third phalanx of the second toe in a constant plantar flexed position. After a time there is an adaptive shortening of the long tendons and lateral ligaments of the joints.

Prognosis.—The prognosis in these cases is indeed gratifying if properly treated. The milder cases will often correct themselves when a proper, well-fitted shoe is worn. In the young child sufficient amount of correction may be gained by constantly stretching the existing contracture, and in fixing an adaptive splint to the sole of the affected toe at night. In the more severe cases we can expect excellent results where a wedge-shaped excision is done, removing the articular cartilage of both sides of the joint, thus allowing the joint to ankylose in extension. Some advise the removal of the toe, which I feel is very unwise; because its absence many times leads to a disability worse than the original hammer-toe, and that is the tendency toward production of halux valgus.

* * *

TREATMENT

Ernest W. Cleary, M. D. (490 Post Street, San Francisco).—This appears to be a very small subject, but it is actually a source of distress out of all proportion to the size of the member involved. Someone has significantly parodied the saying, "Great oaks from little acorns grow" into the equally true statement, "Great aches from little toe-corns grow."

When a toe presents such a deformity that severe contracture of its flexor tendon has brought the end of the toe directly against the sole of the shoe, and the sharp angulation of the interphalangeal joint forces the dorsum of that joint into contact with the upper of the shoe, we call the deformity hammer-toe.

This deformity usually occurs in the second toe, but may be present in any one of the four smaller toes. The objective of treatment is to correct the deformity or to amputate the deformed toe.

Correction of Deformity. — This operation involves invading bone and joint tissue, and the parts should have a similar careful preoperative preparation to that which conscientious surgeons require before more extensive bone operations.

Preparation.—The whole foot back to the ankle should be thoroughly cleansed, with special attention to the area about the toe nail, either for two days prior to operation or twice during the day previous to operation.

Operation.—The mechanical objective of the operation is to shorten the toe so that it can be straightened out and lie in a normal position, with respect to the non-deformed toes and to the shoe. This is accomplished by taking a wedge-shaped mass of tissue with the base of the wedge on the dorsum of the toe and the width of the wedge base sufficient at the skin to remove all of the calloused part usually present over the angulated joint. In the center of the wedge-shaped portion removed from the bone lie the apposed joint surface of the phalanges. Both phalanges should be cut clear through with a small, very sharp chisel, not crushed with bone cutters or bitten away piece-meal with a rongeur. All of the articular cartilages of either face of the articulation should be removed. When the removal of the wedge has been completed and the tip of the toe has been lifted up toward the dorsum of the foot, until the interval left by the removal of the wedge is closed, the toe in this corrected position should be straight and normal in appearance, with relation to the other toes. Usually not more than one very fine, plain catgut suture is necessary to hold the subcutaneous tissues in apposition, and not more than three skin sutures of fine silk or dermal. Immobilization after operation should be definite for a period of at least fourteen days. Such immobilization can be effectively secured by bandaging the toe down firmly to a light aluminum splint on the plantar surface, and such splint should be somewhat racket-shaped, with the broad part fitting back under the ball of the foot. The surest and, in the writer's opinion, most effective form of immobilization is to enclose the foot in a light, well-padded plaster shoe extending back over the heel, but leaving the ankle entirely free. This plaster should be gently molded against the plantar and dorsal surfaces of the operated and adjacent toe. Stitches should be removed not later than the sixth day in order to minimize the degree of scar. For the second two weeks following operation only a very moderate amount of walking in well-fitting shoes should be permitted. The recovery should be sufficiently complete to permit any ordinarily strenuous use of the foot by the end of the fourth week following operation.

Amputation.—The indications for amputation are: (1) the presence of an infection caused by pressure on the dorsally angulated joint, and of such a degree that a satisfactory result from less radical measures is not reasonably to be anticipated; and (2) occurrence of the deformity in a little toe where the preservation of the toe is of lesser consequence and operation for the correction of the deformity is less likely to give a satisfactory result.

Laughter is the saving emotion of the human race, when genuine, for from its presence the cynic flees, the pessimist retreats, the misanthrope is driven to cover. Under its influence the sun shines in dark places, the birds bring again their choicest songs, the flowers lift their smiling faces, and the world becomes once more a worthwhile place in which to live.—Charles E. Whelan.

Conservation of Vision.—As a rule, neither tobacco nor alcohol directly affect the eyes, unless they have first attacked the general health, it is pointed out by Dr. Emanuel Krimsky, of Brooklyn, N. Y., answering some of the questions which are most frequently asked by patients, in a recent issue of "The Sight-Saving Review," quarterly journal of the National Society for the Prevention of Blindness (Summer, 1936).

"And yet," says Doctor Krimsky, "every eye specialist in every book on eye diseases gives prominent mention to blindness of varying degrees of severity from the prolonged and excessive use of either tobacco or alcohol in certain susceptible persons. It is extremely important to recognize blindness from tobacco or alcohol because immediate and complete abstention will often restore vision, unless the case has progressed too far. Wood alcohol blindness is permanent and cannot be cured."

The warning that a black eye may be more serious than funny is made by Doctor Krimsky as follows: "Among children—and sometimes among our alcoholic brethren—a black eye is regarded with honor, in the same sense that German students honor a scar on the cheek as evidence of duelistic prowess. If such an outward discoloration represented the whole story, we might have reason to laugh it away. But the inexperienced can see only skin-deep. It may be that the large majority of these cases can well survive the ordeal, even without having to go to a doctor. But that a certain number of these black eyes also show, on more careful examination, either a fracture of the skull or a hemorrhage into the eyeball with almost sudden blindness, is not generally known. It would seem reasonable, therefore, to submit all these eye injuries to medical examination, to avoid any possibility of permanent harm."

Regarding the danger of eyeglasses breaking and causing an injury to the eyes, he says: "However possible such an accident might seem, strangely enough, it very rarely occurs. Many busy eye specialists have never observed such a misfortune. And the reason is not difficult to understand. Those who wear glasses instinctively value their eyes more than those who do not, and the slightest shock or fear will automatically bring a sudden closure of the lids, with concomitant protection to the eye. For those who are not reassured, it is a comfort to know that lenses may now be obtained which are made of non-shatterable glass. This being the case, it is quite needless for a mother to deny her young child the safe glasses.

"More glasses are being worn now than in the past," Doctor Krimsky explains, "not because eyes are more defective—for they are not—but because the modern human has applied himself to occupations requiring close vision, unlike the pursuits of his forbears who lived on the soil, where close use of the eyes was seldom called into play. While eyes should be reexamined about once a year for glasses, and oftener in cases where eyes change more rapidly, it does not necessarily follow that lenses must be changed. For, while in some persons annual or biennial changes of glasses may be required, in others the same lenses may serve faithfully for ten or fifteen years."

To live in the temper and spirit of a learner, open-minded, unwarped in judgment, free as far as light permits from delusions, eager to explore and inquire, quick to give up a confuted idea and so gain a higher outlook, striving steadily to improve and to grow—these are watchwords of the intellectual life.

Eat less; chew more.
Waste less; give more.
Ride less; walk more.
Go less; sleep more.
Talk less; listen more.
Worry less; work more.
Idle less; think more.
Preach less; practice more.
Clothe less; bathe more.
Scold less; laugh more.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section (Adv. pages 2, 4 and 6).

ASSOCIATION ACTIVITIES

CONSTITUTION AND BY-LAWS

Members are advised to preserve this issue, as it contains the revised Constitution and By-laws of the Association.

In 1929 a committee redrafted the Association's Constitution and By-laws and the House of Delegates adopted it. Since that time, seven years ago, certain amendments have been made at each annual meeting. The most important amendment is the one which deals with disciplinary action and presents a code of procedure. This amendment was adopted this year.

In order that members may have an up-to-date copy of our governing regulations, the entire Constitution and By-laws in revised form is reprinted.

Read it—save it.

* * *

HIPPOCRATES

History transmits the names of but few men whose influence has lasted longer or will continue as long as the physician-philosopher Hippocrates.

"Life is short, and Art is long; the occasion fleeting; experience fallacious and judgment difficult," pertains today as it did centuries ago when uttered by Hippocrates.

Every true physician should frequently ponder upon and remain imbued with the guiding inspiration of the Hippocratic Oath:

> I swear by Apollo the physician, and Aesculapius . . . I will keep this oath . . . I will follow that system of regimen which . . . I consider of benefit to my patients, and abstain from whatever is deleterious and mischievous . . . I will give no deadly medicine to anyone, if asked . . . With purity and with holiness I will pass my life and practice my art . . . Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption . . . Whatever I see or hear, in connection with my professional practice, or not in connection with it . . . which ought not to be spoken abroad, I will not divulge . . .

The oath closes with a prayer that, so long as it is strictly observed, the physician may be blessed of gods and respected of men, but that neither respect nor blessing shall dwell with him who violates it.

Bruce Barton recently wrote:

> What an achievement it is for a man to have set up a standard which has guided the thinking and practice of a whole profession for twenty-three centuries. It's a high standard and, to the eternal credit of physicians, a great majority of them make an honest effort to live up to it.

To which we would add the hope that members of our profession must make that majority so great that the renegade become foundered in the filthy mire of his own makings.

* * *

SOURCES OF INFORMATION

In the front and back advertising sections of each issue readers will find much useful information. Interspersed with the advertisements there are interesting reports from the Board of Medical Examiners, historical items, abstracts of important articles appearing in other publications and other comment.

In the advertisements you will find offerings of all types of medical and surgical supplies, books and approved hospitals and sanitariums. These advertisers are reliable firms and are your patrons. In turn they merit your patronage because they aid in making this journal possible. Patronize them, receive their detail men, favor them. They stand ready to be very helpful to you in many ways. Utilize this source of information. Read each issue from cover to cover. It will be profitable to do so.

* * *

INTERDEPENDENCE

Dr. Olin West, Secretary of the American Medical Association, once stated:

> Our whole purpose of life, of government and everything else these days seems to be to make it as easy as possible for the individual and the group. I think that is one of the evil tendencies of the times. The county medical society ought to do its own work for itself. There are things the State Association can do for it and ought to do for the county society, for the county society cannot do them. There are things the American Medical Association can do because the State Association cannot do them. There are things the state can do for a county, there are things the American Medical Association can do for the state, but ought not to do because those units ought to do their own work for themselves. A county society is only as strong as it makes itself. It is the obligation of every county society to make the strong ones stronger and to devise some plans to make the weak ones stronger. Whatever it may take to do that ought to be done.

This is a direct challenge to all officers and members. Its acceptance and consummation will create a cohesive interdependent, actively functioning group with every unit intermeshing smoothly and powerful for the fullest realization of our organizational objectives. Again it is team work and it's team work we need this autumn and fall. Personal ambitions and quests must be melted in this interdependent group.

* * *

HAVE YOU READ?

The minutes of the Coronado meeting were printed in the July issue. Have you read them? If not you are urged to do so.

This is your organization. Its functions and activities are determined by you through your delegates and by the constitution and by-laws. Your problems, medicine's problems, and the Association and county society problems can be satisfactorily met and dealt with provided that every member understands them. Their nature and meaning and their ultimate effects are outlined and policies are advanced by your committees and officers who devote an untold amount of time in considering and presenting them. These presentations can be found in the reports and minutes of the House of Delegates.

As a member, the duty is yours to familiarize yourself with the affairs of your organization. Having done so, two obligations rest upon every member. The first is to conform to and observe the recommendations and actions approved by your delegates. The second is to give some of your time in bringing about their fullest application. It matters not whether you live and practice in metropolitan centers or in the great wide open spaces of your state, yours is the responsibility to join in a united movement that will record a cohesive activity and an organization that does not simply "resolve" but applies the resolution so as to spell action.

Your suggestions are invited. Your advice is solicited. Your support is our plea.

* * *

MEDICAL PROGRESS

In his daily column, Irwin S. Cobb recently wrote: "I'd rather that every white rat in America should have the bubonic plague twice than that my grandbabies should have it once." So would any other humane and sensible person. Still there are those misguided and deluded persons who are circulating a petition to have an Initiative put upon the ballot this fall to prohibit animal experimentation.

Medical knowledge cannot be conjured out of the air. Unless the antivivisectionists are willing to let investigators experiment upon them, medical men will have to use animals or terminate medical progress.

The following figures indicate the progress that has been made:

In 1836, mortality per 100,000 was:

Smallpox	19.1
Malaria	42.8
Typhoid	65.5
Diphtheria no date, but in 1900 it was	70.5
Tuberculosis	248.3
All deaths	3,390.0

In 1934 we quote the following:

Smallpox	.03
Malaria	.1
Typhoid	.4
Diphtheria	1.9
Tuberculosis	57.5
All deaths	975.0

To these we add the following information from our own department of health:

A comparison of deaths in California in 1911 with deaths in 1935 reveals the tremendous savings that have been effected in human lives during the past twenty-five years, according to a report just issued by the California Department of Public Health in Sacramento.

In the infant group, the report shows that in 1911 10 per cent of all deaths in California were those of infants; in 1935 the percentage of infant deaths was only 5.5 per cent.

In children between 1 and 14 years were counted 7 per cent of all deaths in 1911; in 1935 the percentage in this group dropped to 3.3 per cent.

Among individuals from 15 to 44 years of age the percentage of deaths to the total was 28 in 1911, while in 1935 it was only 16 per cent.

The above figures indicate how preventive medicine and other precautions have contributed to fewer deaths under 44 years and the lengthening of life generally. Above 44 the figures, of course, show the opposite trend. In the group from 45 to 54 years of age, the percentages increased from 12 to 13 per cent; in the 55 to 65 year group the percentage increased from 13 per cent in 1911 to 17 in 1935, and above 65 it increased from 29 to 44 per cent.

In other words, 15 more persons out of every hundred live bepond 65 today than did in 1911.

The report further states that life is safer and longer in America than in any except the Scandinavian countries of Europe. People live from one to two years longer on the average in the United States than in England, France, Italy or Germany. This is not due alone to a favorable natural environment, but to no small degree from the cultivation and utilization of preventive medicine.

Surely medical progress has been made. Further progress must not be obstructed by misguided fools.

CONVENTION ECHOES

Our members will be interested in these letters. They are in answer to our letter thanking them for participating in our exhibit division.

Coca-Cola Company,
Atlanta, Ga.

California Medical Association,
Dr. Frederick C. Warnshuis, Secretary,
450 Sutter Street,
San Francisco, California.

Dear Doctor Warnshuis:

This is my first opportunity to thank you for your letter of June 3 inviting us to offer any suggestions concerning your commercial exhibit and its operation, in order that you might take such suggestions into consideration in planning for 1937.

We feel that our participation in your recent convention at Coronado was justified, and I am hopeful that the company may again wish to participate with you next year. We received many favorable comments about our booth, the way it was handled, etc., as well as complimentary references to the handling of the convention as a whole. This reflects great credit upon you and others who had to do with making the convention the success it was.

We do not have any suggestion to offer as to any changes, although we greatly appreciate your courtesy in affording the opportunity; and with best wishes, we are,

Most cordially,
COCA-COLA COMPANY.
ROY GENTRY, *Assistant to Mr. Harrison Jones.*

* * *

June 10, 1936.

Dr. F. C. Warnshuis, Secretary,
California Medical Association,
450 Sutter Street,
San Francisco, California.

Dear Doctor Warnshuis:

Thank you for your letter of June 3 in which you extended the Association's appreciation for our coöperation.

We thoroughly enjoyed our participation in the exhibit, but have no additional suggestions that we can make at this time.

With all best wishes, I am,

Sincerely yours,
DICTOGRAPH PRODUCTS COMPANY, INC.
DAN D. HALPIN,
General Sales Manager, Acousticon Division.

* * *

June 8, 1936.

Dr. Frederick C. Warnshuis, Secretary,
California Medical Association,
450 Sutter Street,
San Francisco.

Dear Doctor Warnshuis:

Thanks for your letter of June 3 in reference to the California Medical Association meeting in San Diego.

Mr. Davis, who represented us there, reports that it was a good meeting, allowing us an opportunity to meet many men who have been of help to us. It was certainly a better meeting for the exhibitors than last year's convention at Yosemite, which I attended.

Perhaps we are used to more seriousness in our medical meetings in the Mid-West and East, for it seems as though there is much more entertainment connected with your meetings than with ours. That seems to be the greatest difficulty as far as the exhibitors are concerned—namely, that the men are not in attendance at the meeting place and do not come through and visit the exhibits to the same extent as they do here. We exhibitors go to a lot of expense and time to be with you. It is a pleasure to be at your meetings and to meet a number of the men, but I believe we would be more satisfied if we could count on a larger percentage of the attending physicians to give attention to the exhibitions. Perhaps the fact that all your meetings are held at resort places—Yosemite, San Diego, Del Monte, etc.—is the reason for the greater holiday attitude. Your meetings held in San Francisco and Los Angeles at a convention hall centrally located would be an interesting experiment.

Please express my thanks to your committee and the officers of the California State organization for their courtesy and for the coöperation given us at your meetings. I hope sincerely that we will be with you again next year.

Sincerely yours,

BILHUBER KNOLL CORP.

E. Bilhuber.

* * *

California Medical Association,
450 Sutter Street,
San Francisco, California.
Attention: Dr. F. C. Warnshuis.

Gentlemen:

We acknowledge with thanks receipt of your letter of June 2, and wish to advise that according to report made to us by our representative, Mr. Callais, who was in attendance, your meeting was entirely satisfactory from our viewpoint, and in fact he particularly mentions that the comment among the exhibitors was that your 1936 session was one of the best meetings that they had ever attended.

We have requested Mr. Callais to send to us any suggestions he may be in a position to make concerning your commercial exhibits and their operation, and if any suggestions are advanced we will be very glad to forward them to you.

With very best wishes for the success of your association, we are,

Yours very truly,

Bard-Parker Company, Inc.

* * *

June 4, 1936.

Dr. F. C. Warnshuis,
450 Sutter Street,
San Francisco.

Dear Doctor Warnshuis:

The meetings of the Surgical Section of the recent meeting of the California Medical Association were well attended. At one time there was an attendance of well over 200.

I should like to suggest that, in the future, at least some papers from the Pathologic, Pediatric, Gynecologic and Radiologic Sections be given in the Surgical Section. It seems to me that there are too many sections going on at the same time. I feel that some of the smaller sections could be combined with surgery or with medicine without having those sections lose their own identity, perhaps letting them have one or two meetings in which they could take up the more theoretical problems of their own sections.

Yours very truly,

H. Glenn Bell, M.D.

* * *

June 3, 1936.

Dr. F. C. Warnshuis, Secretary,
California Medical Association,
450 Sutter Street,
San Francisco.

My dear Doctor Warnshuis:

As attorney for the Rhythm Foundation, please accept my personal thanks and the thanks of the Rhythm Foundation, first, for the opportunity of exhibiting at the recent convention of the California Medical Association at Coronado, and second, for the coöperation you extended to the Rhythm Foundation as exhibitors at the convention.

In the space of three and one-half days at the convention, the Rhythm Foundation distributed over 1,500 pamphlets, sold several hundred calculators, and took orders for approximately 100 books by Doctor Ogino, one of the originators of the Ogino-Knaus theory of birth regulation.

As for myself personally, I enjoyed the convention very much, for it enabled me to meet doctors from all over the state, and also a few doctors from out of the state. The convention also made me realize that the medical profession contains some of the finest men in the community, and enabled me to receive a very liberal education on many phases of medicine in the short space of three days.

I have attended many conventions, but yours was one of the best in my experience, and I trust we will be with you again at Del Monte next year.

Very truly yours,

E. K. Gubin.

HOTELS—DEL MONTE—1937 ANNUAL SESSION

The following arrangements have been made for hotel accommodations for our annual session in Del Monte, May 2-5, 1937.

1. Hotel Del Monte will be general headquarters.

2. *All* hotel reservations will be made by and through Mr. Carl Stanley, manager of Hotel Del Monte.

3. Members will select the accommodations desired in the following list of hotels and then request Mr. Stanley to obtain and confirm them.

4. Do not write to the hotels. *Write only to Mr. Stanley,* who is in sole charge of hotel reservations.

* * *

Luncheon	65c
Dinner	85c

* * *

INQUIRIES

For informative purposes the following indicates the average and nature of the inquiries received daily at the Association Headquarters office and which are, as a rule, answered on the day of receipt. They come from lay people as well as from physicians.

1. Names of state private mental sanitariums.
2. Local tenens wanted for three months.
3. Formula of an advertised patent remedy.
4. Radio broadcasting station asking merit of certain "water crystals" that manufacturer wishes to advertise over radio.
5. Present address of a physician.
6. Names of plastic surgeons in a given locality.
7. Reputation and standing of a certain school for backward children.
8. Request for locations.
9. Reciprocity rights.
10. Value of "Rhythm" theory.
11. Legal problem.

Some days as many as twenty to thirty such inquiries are received. The Association's offices are glad to receive and answer such requests. The endeavor is made to cause the public and the profession to learn that there is a central clearing place where dependable information can be obtained.

* * *

DISCIPLINARY PROCEDURE

After a year of investigation, study and drafting the Code of Disciplinary Procedure presented, by Doctor Roblee's committee, to the House of Delegates, was adopted at the Coronado session. That code is now a part of the by-laws of our Association.

Under instructions of the Council the following bulletin has been sent to every county secretary:

SPECIAL BULLETIN

To County Secretaries:

The attention of your county medical society is directed to the following enactments:

1. *Disciplinary Procedure*: The House of Delegates adopted as an amendment to the State Association's by-laws, a code of disciplinary procedure. (See minutes in July CALIFORNIA AND WESTERN MEDICINE.) This code must be observed when disciplinary action is instituted.

2. *County Society Action:* The Council adopted the following resolution:

"The procedure to be followed by this society with respect to censure, suspension or termination of membership of a member of this society shall be the procedure now or hereafter contained or provided for by the by-laws of the California Medical Association, as now existing, and as the same may hereinafter be amended. This section shall supersede any of the provisions of these by-laws in conflict herewith."

3. *County By-Law Amendments:* Each county society is, therefore, directed to comply with these enactments. Early action should be taken to amend your by-laws to cause them to conform to these state regulations and provisions.

It is extremely important that there be little delay in conforming to these instructions.

By direction of the Council.

Frederick C. Warnshuis, M.D.,
Secretary.

Fourteen years ago your secretary, in his Speaker's address to the American Medical Association House of Delegates, made the following recommendation:

"Our members have a direct obligation to the Association and to their associates. Precedents and rules of guidance for each individual must be established and must be observed by the whole without exception or favor."

At the recent American Medical Association meeting, Kansas City, Dr. Olin West declared that it was incumbent upon each constituent unit to look to the quality and character of its members and that those who violated our standards of ethics and professional conduct should be weeded out and be deprived of membership.

The Judicial Council of the American Medical Association is to be empowered to initiate proceedings against members and Fellows of the American Medical Association who are unprofessional in conduct and against whom their county and state organizations fail to institute proceedings.

President Pallette has stated: "There is something wrong with a licensed physician who is not a member of his county medical society and the public is learning to look askance upon the non-member."

We have repeatedly stated that society membership is a valuable asset. Courts have expressed similar opinions. We must maintain high standards of membership and discontinue the rights of membership to those who fail to live up to our principles of ethics, policies and standards.

As far as we know, California is the first state to formulate a code of procedure conforming to the law of the courts for disciplinary purposes. Our thanks are due Doctor Roblee and his committee for their excellent work.

County societies must not delay amending their by-laws so as to cause them to conform to the new regulations governing membership.

Minutes of the One Hundred and Forty-seventh Meeting of the Executive Committee of the California Medical Association

1. The Executive Committee of the Council of the California Medical Association met in monthly session in San Francisco on June 20, 1936, with the following members present:

President Edward M. Pallette, President-elect Howard Morrow, Speaker William W. Roblee, Chairman of the Executive Committee Karl L. Schaupp, Chairman of the Council Morton R. Gibbons, Chairman of Public Relations Committee Charles A. Dukes, Editor George H. Kress, Secretary F. C. Warnshuis and General Counsel Hartley F. Peart.

There were also present by invitation, J. B. Harris, E. T. Remmen, T. H. Kelly, Axcel E. Anderson, Louis A. Packard, Fred B. Clarke, Glenn Myers, C. G. Toland, Dewey R. Powell and Mr. Ben Read.

2. This being the annual meeting of the committee for the election of a chairman, the meeting was called to order by the secretary of the State Association, who asked for nominations for the office of chairman.

President Pallette nominated Karl L. Schaupp for the chairmanship. This nomination was seconded by Chairman of Public Relations Committee Dukes. There being no further nominations, a vote was taken and Doctor Schaupp was unanimously elected chairman of the Executive Committee for the ensuing year.

Doctor Schaupp then assumed the chair and the meeting thereupon proceeded.

3. **1937 Annual Meeting.**—The secretary presented information as to dates for holding our annual meeting in 1937 in Del Monte.

On motion of Chairman of Public Relations Committee Dukes, seconded by Councilor Gibbons, the dates of May 2, 3, 4 and 5, 1937, were designated as the dates for our sixty-sixth annual session.

4. **County Hospitals.**—Councilor Harris, chairman of the Committee on Public Relations, presented the problem concerning the movement which seeks through initiatives to open all county hospitals of this state.

Discussion was engaged in by Mr. Ben Read, of the Public Health League, and several of the committee.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Speaker Roblee, that the Strategy Committee appointed by the president, in accordance with the action of the Council, under the supervision of and in coöperation with the Legislative Committee, be authorized to adopt such plans and institute such measures as will bring about the defeat of this legislative proposal. Carried.

On motion of Gibbons, seconded by Dukes, the president was instructed to appoint five southern members. Carried.

Dr. Dewey Powell, representing the San Joaquin County Medical Society, was present and submitted a statement as to the situation in that county and requested information, as well as advice, as to the attitude that is to be taken by the San Joaquin County Medical Society. The information requested was imparted to Doctor Powell for transmittal to the members of his county organization.

Upon motion of President Pallette, seconded by Councilor Gibbons, the Committee on Public Policy and Legislation, subject to the approval of the Auditing Committee, was granted an appropriation of $1,000 for preliminary campaign expenses.

5. **Supplement to Journal.**—The secretary reported that the supplement to California and Western Medicine, approved by the Council at its Coronado meeting, would cost approximately $350 and that the sending of this supplement as a separate pamphlet to all members would cost approximately $424. Discussion was had as to the advisability of mailing this supplement as a part of California and Western Medicine.

It was moved by Councilor Gibbons, seconded by Chairman of Public Relations Committee Dukes, that the matter of publication of this tax information material be referred to the Committee on Public Policy and Legislation and its associated Strategy Committee for their consideration and recommendation, whether it shall be published as a supplement to the official journal or shall be sent to our members under the auspices of the Public Health League or under the auspices of the Legislative Committee, and that the recommendation of the committee be transmitted to the Council. Carried.

6. **Committee on Activities and Expenditures.**—In accordance with councilor action, Councilor Gibbons stated that he had appointed as members of the Committee on Major Activities and Expenditures of the Association, C. E. Schoff, chairman; William W. Roblee and T. Henshaw Kelly.

It was moved by Chairman of Public Relations Committee Dukes, seconded by President-elect Morrow, that the appointments be approved. Carried.

7. **Forestry Medical Corps.**—The secretary reported on the reorganization of the Forestry Medical Corps and stated that the matter of the revocation of the charter of the old corps had been referred to Doctor Harris and Mr. Peart.

8. **Disciplinary Procedure.**—It was moved by Speaker Roblee, seconded by Councilor Gibbons, that county societies adopt the following amendment to their by-laws:

"The procedure to be followed by this society with respect to censure, suspension or termination of membership of a member of this society shall be the procedure now or hereafter contained or provided for by the by-laws of the California Medical Association, as now existing, and as the same may hereafter be amended. This action shall supersede any of the provisions of these by-laws in conflict therewith." Carried.

9. Financial Statement.—Financial statement for the month of May, 1936, as mailed to all members of the Council, was approved.

10. Library Contributions.—It was moved by President Pallette, seconded by Councilor Gibbons, that the California Medical Association donate 25 cents per member to Lane and Barlow Medical Libraries. Carried.

11. Appeals.—The secretary stated that a notice of appeal from the decision of the California Medical Association to the Judicial Council of the American Medical Association had been received from Ferd Callison, and that the attorney for the Kern members stated that he believed the deciplined members would appeal to the American Medical Association.

On motion of Editor Kress, seconded by Councilor Gibbons, the secretary was authorized to write to the secretary of the American Medical Association suggesting that it would be opportunely convenient for the California Medical Association if the Judicial Council could hold its hearings during the time of the annual conference of state secretaries and editors, at which time representatives of the California Medical Association would be present to make such oral statements as might be requested. Carried.

12. Physical Therapy Report.—The secretary presented the annual report of the Committee on Physical Therapy, and on motion of President Pallette, seconded by Speaker Roblee, the committee was continued. Carried.

13. Vivisection.—Letter from the San Diego society regarding vivisection as brought up by the Parent-Teachers' Association was presented. It was moved by Councilor Gibbons, seconded by Chairman of Public Relations Committee Dukes, that the correspondence be referred to the Committee on Public Policy and Legislation. Carried.

14. Pre-Convention Bulletin.—Upon motion of Editor Kress, seconded by Chairman of Public Relations Committee Dukes, the question of publishing a Pre-Convention Bulletin was referred to the next regular meeting of the Council.

15. Minutes of House of Delegates.—It was moved by Chairman of Public Relations Committee Dukes, seconded by Speaker Roblee, that the matter of publication of minutes of the House of Delegates verbatim be discussed at the next regular meeting of the Council and that the minutes of the sixty-fifth annual session be published in full in the July Journal. Carried.

16. Journal Costs.—The secretary reported, for the information of the Council, that the cost of publication of eight additional pages, based on 5,000 run of Journal, was $70; sixteen pages, $135, twenty-four pages $187, and thirty-two pages $250.

17. Cuts for Journal.—On motion of Editor Kress, seconded by President Pallette, the following resolution was adopted:

Resolved, That in all matters having to do with the printing and other typographical and editorial phases and work of CALIFORNIA AND WESTERN MEDICINE, sole authority and responsibility shall be vested in the editor, subject to instructions from the Council or Executive Committee.

18. Professional Cards.—The secretary presented correspondence from a member regarding publication of a professional card in the Journal, and stated that the Council had previously refused publication of said cards.

It was moved by Councilor Gibbons, seconded by Chairman of Public Relations Committee Dukes, that the previous policy of the Council rejecting publication of such professional cards be reaffirmed. Carried.

19. Nevada Society.—Editor Kress presented draft of a letter to be sent to the Nevada Society in accordance with action taken by the Council at the Coronado session.

It was moved by Councilor Gibbons, seconded by Chairman of Public Relations Committee Dukes, that the letter as presented be approved. Carried.

20. Adjournment.—There being no further business, the meeting adjourned.

KARL L. SCHAUPP, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

CONSTITUTION AND BY-LAWS OF THE CALIFORNIA MEDICAL ASSOCIATION

CONSTITUTION*

ARTICLE I.—NAME

Section 1.—Name

The name of this organization is the California Medical Association.

ARTICLE II.—PURPOSES AND GENERAL ORGANIZATION

Section 1.—Purposes

The purposes of this Association are to promote the science and art of medicine, the protection of public health, and the betterment of the medical profession; to promote similar interests of its component county societies; and to unite with similar organizations in other states and territories of the United States to form the American Medical Association.

Section 2.—Organization

This Association, as a state unit of the American Medical Association, and as the state expression of the component county societies of California, shall have three major divisions: one, the Association as a whole, as when it meets in general session; two, the Scientific Assembly and its subordinate or related bodies; and, three, the House of Delegates and its subordinate or related bodies.

ARTICLE III.—COMPONENT COUNTY SOCIETIES

Section 1.—Component County Societies to Be Chartered

Component County Societies shall consist of those county medical societies which hold charters from the Association.

Section 2.—Geographical Scope

Only one component county society shall be chartered in any one county of the state; provided, however, when in the judgment of the House of Delegates it is deemed to be to the best interests of this Association, a charter may be granted to a component county society comprising two or more counties.

ARTICLE IV.—MEMBERSHIP

Section 1.—Kinds of Members

The members of the Association shall consist of the following:

(a) Active Members

Qualifications.—Active members shall comprise all active members of all the component county societies. No person shall be eligible for election to active membership in a component county society unless he shall hold the degree of doctor of medicine issued to him by an institution of learning accredited at the time of conferring such degree by the American Medical Association or the Association of American Medical Colleges. He must also hold an unrevoked license to practice medicine and surgery in the State of California; provided, however, that subject to the minimum qualifications prescribed by this Constitution and the By-Laws, each component county society shall be the exclusive judge of the qualifications of the members thereof.

Rights.—An active member shall have the right of suffrage and all other rights and privileges of the Association.

(b) Associate Members

Qualifications.—Associate members may be elected by the Council, upon recommendation of the component societies of the counties in which the associate members reside, from those doctors of medicine engaged in teaching or research work or holding positions in the Federal Service or otherwise, who are not licensed to practice medicine and surgery in the State of California and hence are not eligible for active membership, and from other persons engaged in medical teaching or research or other scientific work contributing to medicine and the public health.

---

* This is the first official revision of the Constitution and By-Laws adopted on May 8, 1929. This revision is designated: Second Printing (Revised).

See also editorial comment in this issue (page 118).

Obligations and Rights.—Associate members shall have all the rights and privileges of active members except the right to vote or hold office. The dues of associate members shall be one-half of the dues of active members; and their dues to their respective component county societies (when such associate members are admitted to membership therein) shall be fixed by such component county societies.

(c) Retired Members

Qualifications.—Retired members of the California Medical Association shall be elected by the Council on the recommendation of any component county society from those active members thereof who cease the practice of medicine for reasons satisfactory to such component county society and the Council, and who shall have been active members of the Association for ten years or more prior thereto.

Obligations and Rights.—The dues of retired members shall be fixed by the Council.

Retired members shall be entitled to receive the publications of the Association at such rates as the Council from time to time may determine.

Retired members shall not have the right to vote or to hold office.

(d) Honorary Members

Qualifications.—The House of Delegates on recommendation by the Council may elect as honorary members any persons distinguished for their services or attainments as doctors of medicine or in the field of public health, or for research or other scientific work contributing to medicine.

Obligations and Rights.—Honorary members shall not pay dues, and shall not have the right to vote or to hold office.

ARTICLE V.—HOUSE OF DELEGATES

Section 1.—Composition of House of Delegates

The House of Delegates shall consist of:

(a) Delegates elected by the component county societies; and

(b) The officers of the Association enumerated in Section 1 of Article X of this Constitution.

Section 2.—Basis of Representation of Component County Societies

Each component county society shall be entitled to be represented by one delegate and one corresponding alternate for every fifty active members thereof, and also by one delegate and one corresponding alternate for each fraction of fifty active members in excess of fifty or multiples thereof as of the first day of November of the year preceding a current annual session.

Every component county society having less than fifty active members shall be entitled to be represented by one delegate and one corresponding alternate.

Section 3.—Alternates

One alternate eligible to service if any delegate of the delegation of a component county society is disqualified or fails to attend the meeting, shall be elected for each delegate by each component county society.

Section 4.—Terms of Delegates and Alternates; One Half Elected Each Year

Delegates and alternates shall be elected by the several component county societies respectively for a term of two years; one-half of the delegates and alternates representing each component county society as near as may be shall be elected each year.

Section 5.—Qualifications of Delegates and Alternates

Every delegate and alternate must be in good standing as an active member of the Association and of his component county society, and have been such at least two years immediately preceding his election.

Section 6.—Quorum

Thirty-five members shall constitute a quorum of the House of Delegates.

Section 7.—Legislative Functions of House of Delegates

The House of Delegates shall be the legislative body of the Association.

It shall at the regular annual session thereof elect the President-Elect, the Speaker and the Vice-Speaker of the House of Delegates, and such other officers as may be specified in this Constitution and By-Laws.

In accordance with the Constitution and By-Laws of the American Medical Association it shall elect the Delegates of the Association to the House of Delegates of the American Medical Association.

Section 8.—Issuance and Revocation of Charters

It shall issue component county society charters, upon the recommendation of the Council, to county medical societies which it deems and finds eligible therefor, and may, after notice to any component county society and due and proper hearing, revoke any such charter for cause.

Section 9.—Regrouping of Component County Societies Into the Councilor Districts

At least once in every ten years upon recommendation of the Council or upon its own initiative, the House of Delegates shall form and group or regroup the component county societies into the number of Councilor Districts as provided by the Constitution.*

Section 10.—Division of Scientific Work

The House of Delegates, upon recommendation from the Council or on its own initiative, shall provide for the division of the scientific work of this Association into appropriate sections.

Section 11.—Annual Per Capita Assessment of Dues

The House of Delegates at its regular annual session shall fix the amount of the annual per capita assessment of dues upon the active members.

Section 12.—Budget

The House of Delegates shall approve an annual budget to be submitted to it by the Council.

Section 13.—Councilor District Societies

The House of Delegates, upon recommendation of the Council or on its own initiative, may provide for the organization of such Councilor District Societies as will promote the best interests of the profession, such Councilor District Societies to be composed exclusively of members of component county societies.

Section 14.—Other Powers and Duties

The House of Delegates shall have such other powers and perform such other duties as are provided by the Constitution and the By-Laws.

ARTICLE VI.—REFERENDUM

Section 1.—How Referendum May Be Brought About

The House of Delegates at any meeting thereof at any regular or special session may by a two-thirds vote of all of its members, or the Council at any meeting thereof may by a three-fourths vote of all its members, submit any question, matter or proposition to all of the active members of the Association by mail, and a majority of the votes cast by mail by such members of the Association shall be final and bind and govern the Association upon the question, matter or proposition so submitted to the membership.

---

* Component County Societies comprising the nine councilor districts, as approved by the House of Delegates, May 8, 1929, are as follows:

District No. 1.—Imperial, Orange, Riverside, San Diego, San Bernardino.[1]**
District No. 2.—Los Angeles.[1]
District No. 3.—Kern, San Luis Obispo, Santa Barbara, Ventura.
District No. 4.—Calaveras, Fresno, Inyo, Kings, Madera, Mariposa, Merced, Mono, San Joaquin, Stanislaus, Tulare, Tuolumne.
District No. 5.—Monterey, San Benito, San Mateo, Santa Clara, Santa Cruz.
District No. 6.—San Francisco.
District No. 7.—Alameda and Contra Costa.
District No. 8.—Alpine, Amador, Butte, Colusa, El Dorado, Glenn, Lassen, Modoc, Nevada, Placer, Plumas, Sacramento, Shasta, Sierra, Sutter, Tehama, Yolo, Yuba.
District No. 9.—Del Norte, Humboldt, Lake, Marin, Mendocino, Napa, Siskiyou, Solano, Sonoma, Trinity.

** See page 200 for explanatory note concerning amendments and the key number references to minutes of the House of Delegates in which the adoption of the amendments are noted.

Section 2.—Council to Determine Form of Referendum; Time of Voting; Canvass

The Council shall prescribe, fix and determine the form of the question, matter or proposition so referred to the active members and the time within which such vote shall be cast.

Each vote must be in writing and the same must be placed in a sealed envelope, the envelope bearing on the corner thereof the name of the voter. The envelope shall be mailed or delivered to the Secretary's office. The canvass thereof shall be made under the direction of the Council.

Section 3.—Referendum on Action of House of Delegates

The action of the House of Delegates shall be final and binding upon all members of the Association unless a referendum as herein provided is voted by the House of Delegates by a vote of at least two-thirds of the members thereof, at the same session at which the action was taken or the vote or resolution was had or adopted, or unless the Council by a three-fourths vote of all its members, shall within the period of thirty days after adjournment of such meeting of the House of Delegates vote to hold a referendum on such action, vote or resolution of the House of Delegates.

ARTICLE VII.—COUNCIL AND EXECUTIVE COMMITTEE

Section 1.—The Council

The Council shall consist of the Councilors, and ex-officio: the President, the President-Elect, the Speaker of the House of Delegates, and the Chairman of the Committee on Public Relations,[2] each with all the rights of a Councilor.

Subject to the provisions herein, the Secretary-Treasurer and the Editor shall also be ex-officio members of the Council, but without the right to vote.

The nine district councilors shall be elected as follows: Prior to the time set for the election of District Councilors, the delegates of each councilor district for which a councilorship is about to become vacant, shall meet, organize and in due form elect one or more members of the said councilor district, as a nominee or nominees for the said vacancy in such councilor district. Such nomination or nominations shall be submitted in writing, signed by at least two delegates who were present at such meeting, and shall be given to the Secretary-Treasurer, by him to be transmitted to the House of Delegates. The House of Delegates may make additional nominations from the floor of the house, and in the event that the delegates from a councilor district fail to submit a nomination or nominations, shall on its own account proceed to make nominations for each district councilor vacancy; and a vote shall then be taken by the House of Delegates to determine who shall be elected to the vacant councilorship.

All councilors-at-large shall be elected one by one from nominations made on the floor of the House of Delegates. Not more than two Councilors-at-large shall be elected from any one councilor district; provided, however, that when any one councilor district shall consist of a component county society having 1500 or more members, two of the councilors-at-large shall be elected from its membership.

Section 2.—Organization

At the first meeting of the Council held after the adjournment of the last meeting of the House of Delegates at the regular annual session of the Association, the Council shall organize by the election of one of the Councilors as Chairman of the Council who shall serve as such up to the first Council meeting held after the adjournment of the last meeting of the House of Delegates of the next succeeding regular annual session of the Association; and a Vice-Chairman who shall hold office for the same term, and who, in the absence of the Chairman, shall perform the duties of the Chairman.

The Secretary-Treasurer of the Association shall serve as the secretary of the Council.

Section 3.—Quorum

Nine Councilors shall constitute a quorum.

Section 4.—Regular Councilor Meetings; When and Where Held

The Council shall meet on the day preceding the annual session of the Association and daily during such session, and shall also hold at least three other regular meetings during the year, at least one of which shall be held in the southern part of the state.

The time and place of such meetings shall be fixed by the Council at a previous meeting and at least ten days' notice by mail shall be given each Councilor by the Secretary of the time and place of such regular meetings.

Section 5.—Special Council Meetings; Notice Where Held

Special meetings of the Council may be called by the Chairman at any time and he shall call such meeting upon the written request of at least three Councilors filed with the Secretary, stating the object of the proposed meeting. Written notice of the time, place and object of such meeting shall be given by the Secretary to all members of the Council at least seven days prior to such meeting. All special meetings of the Council shall be held at the office of the Association unless another place is selected by majority vote of all members of the Council.

Section 6.—Other Duties

(a) General Powers and Functions

Subject only to provisions of this Constitution and By-Laws and all resolutions and enactments of the House of Delegates, the Council shall be vested with full and complete power and authority to manage, control, use, invest, reinvest, lease, make contracts in respect of, and concerning, convey, give, grant, transfer or otherwise dispose of all property and assets of whatever kind or nature owned by the Association and shall also be vested with full and complete power and authority to do and perform all acts and to transact all business for and on behalf of the Association and to manage and conduct all the work and activities of the Association in carrying out the purposes thereof.

(b) Budget Report

Through its chairman, as otherwise provided, it shall submit a budget for each ensuing year to the House of Delegates.

(c) Annual Report

At the first meeting of the House of Delegates at each annual session it shall make a report on the state of the Association and its work and proceedings for the preceding year.

(d) Salaries of Officers and Employees

The Council shall fix the compensation of the officers, representatives and employees of the Association.

Section 7.—Auditing Committee

The chairman of the Council, subject to its approval, shall appoint an auditing committee of three members, designating one of the members as its chairman.

The Auditing Committee shall inspect all bills and claims against the Association, and no bill or claim shall be paid except upon voucher or draft having the approval of at least two of the three members of the auditing committee; provided, however, that any bill or claim may be paid without the approval of any member of the auditing committee by a majority vote or written approval of a majority of all the members of the Executive Committee.

Section 8.—Executive Committee

The Executive Committee shall consist of the President, the President-Elect, the Speaker of the House of Delegates, the Chairman of the Council, the Chairman of the Auditing Committee, the Chairman of the Committee on Public Relations,[3] the Secretary-Treasurer and the Editor.

(a) Officers

The Executive Committee shall elect its own chairman. The Secretary-Treasurer of the Association shall act as the secretary thereof.

(b) Quorum

Four members shall constitute a quorum.

(c) Duties and Powers

The Executive Committee shall aid and assist the officers and the Council in the transaction of the business of the Association in the intervals between the meetings of the Council. It shall have such additional duties and powers as are imposed upon it by this Constitution and the By-Laws. It shall have such advisory powers and such other duties as the Council shall from time to time determine.

(d) Records

It shall keep a record of its proceedings and report the same to the Council.

(e) Executive Committee Meetings

The Executive Committee shall meet on call of the President, the Chairman of the Council or the Chairman of the Executive Committee, on forty-eight hours' notice by mail or telegraph to the members thereof, if the meeting is to be held at the office of the Association; otherwise on at least three days' notice of the time and place of meeting.

(f) Authorization or Approval of Council Necessary

All of its acts and proceedings, unless expressly provided for by this Constitution and the By-Laws, shall be expressly authorized or ratified and approved by the Council.

ARTICLE VIII.—SCIENTIFIC ASSEMBLY

Section 1.—Objects

The Scientific Assembly of the California Medical Association is the convocation of its members for the presentation and discussion of subjects pertaining to the science and art of medicine.

Section 2.—Sections

The Scientific Assembly shall be divided into sections, each section representing that branch of medicine described in its title.

Section 3.—Creation of New Sections

New sections may be created or existing sections discontinued by the House of Delegates. The Scientific Assembly and its sections shall be conducted in accordance with the provisions of this Constitution and the By-Laws, and such other instructions by the House of Delegates or the Council as may not be in conflict therewith.

ARTICLE IX.—SESSIONS AND MEETINGS

Section 1.—Annual Sessions of the Association, of the House of Delegates, and of the Scientific Assembly

The Association shall hold an annual session, during which there shall be at least two general meetings, open to all registered members, delegates, and guests.

At such annual session the House of Delegates and Scientific Assembly of the California Medical Association shall also hold meetings.

Section 2.—Time and Place of Annual Session

The time and place for holding each annual session shall be fixed by the Council, and due notice thereof shall be printed in the official journal of the Association.

Section 3.—Special Meetings; How Called; Notice Thereof

Special meetings of the Association may be called by a three-fourths vote of all the members of the House of Delegates or of the Council, and if so called shall be held at such time and place as the Council shall fix.

The Council shall cause written notice thereof, stating the object of the meeting, to be sent by United States mail, postage fully prepaid, to each active member of the Association, addressed to him at his office or place of residence as shown by the records of the Secretary's office, at least fifteen days prior to the date of meeting.

Section 4.—Regular Annual Sessions of House of Delegates

(a) Annual Session

The House of Delegates shall hold a regular annual session consisting of at least two meetings, the second whereof shall not be convened until at least twenty-four hours shall have elapsed subsequent to the convening of the first meeting.

(b) Place of Meeting

The regular annual session of the House of Delegates shall be held at the same place as the regular annual session of the Association, and the Council shall fix the times for the first two meetings.

(c) Notice of Meeting

The same notice shall be given of such sessions and the meetings thereof as that prescribed for the regular annual sessions of the Association.

Section 5.—Special Meetings of House of Delegates

(a) How Called

Special meetings of the House of Delegates may be called at any regular or special meeting of the Council, by a two-thirds vote of all the members of the Council, or by written call stating the object of the meeting, filed with the Secretary in the office of the Association and signed by one-half or more of the members of the House of Delegates.

(b) Time and Place of Meeting

Upon the filing of such call with the Secretary, the Council shall within thirty days thereafter fix the time and place for the holding of such special meeting and cause written notice thereof stating the object of the meeting to be sent by United States mail, postage fully prepaid, to each member of the House of Delegates, addressed to him at his office or place of residence, as shown by the records of the Secretary's office, at least fifteen days prior to the date of meeting.

Section 6.—All Meetings to Be Held in California

All meetings shall be held within the State of California.

Section 7.—Meetings Open to Members

All meetings of the House of Delegates, other than executive meetings thereof, shall be open to all members of the Association.

ARTICLE X.—OFFICERS

Section 1.—Officers

The officers of this Association shall be a President, a President-Elect, a Secretary-Treasurer, a Speaker of the House of Delegates, a Vice-Speaker of the House of Delegates, an Editor, the Chairman of the Committee on Public Relations,[4] and fifteen Councilors (six of the fifteen Councilors being elected as at large, and nine from Councilor districts, as herein provided.)

Section 2.—President-Elect—When and How Elected; Term of Office

The House of Delegates at the regular annual session thereof shall elect the President-Elect to serve until the adjournment of the final meeting of the House of Delegates at its next regular annual session. At the conclusion of the final meeting of the House of Delegates at its next regular annual session, such President-Elect shall assume the office of President, and serve as such for the term of one year thereafter, or until his successor assumes office.

Section 3.—Speaker and Vice-Speaker of House; When Elected; Term of Office

The House of Delegates shall at the regular annual session thereof elect a Speaker of the House of Delegates and a Vice-Speaker of the House of Delegates, each to serve for the term of one year, or until their successors are elected and assume office. The Speaker and Vice-Speaker shall be members of the House of Delegates at the time of their election.

Section 4.—Officers as Ex-Officio Members of Council

The President, President-Elect, Speaker of the House of Delegates, and Chairman of the Committee on Public Relations[5] shall be ex-officio members of the Council, with all the rights of Councilors.

The Secretary-Treasurer and the Editor shall also be ex-officio members of the Council, but shall not have the right to vote; provided, that a Secretary-Treasurer or an Editor who is not a member of the Association shall not be an ex-officio member of the Council.

Section 5.—Terms of Councilors

Each Councilor shall be elected for a term of three years.

Section 6.—Councilors to Be Elected in Different Years

Three District Councilors and two Councilors-at-Large shall be elected each year.

Section 7.—Councilors; Method of Election

When Councilor positions become vacant, or when regular Councilor terms expire and necessitate an election, then such elections shall always be for specific councilorships, one by one, until all such emergency or regular vacancies shall have been filled.

Section 8.—Council Appointments to Fill Vacancies in Office

The Council by appointment shall fill any vacancy in office not otherwise provided for in this Constitution or the By-Laws, which occurs during the interval between the annual sessions of the House of Delegates. Such appointee shall serve until his successor has been elected and has assumed office.

Section 9.—Election of Councilors on Adoption of This Constitution

Upon the adoption of this Constitution, the House of Delegates shall proceed to elect Councilors as follows: At the annual meeting at which this Constitution is adopted, the Councilors of the First, Fourth and Seventh Districts and two Councilors-at-Large shall be elected; in the succeeding year the Councilors of the Second, Fifth and Eighth Districts and two Councilors-at-Large shall be elected; and in the year succeeding, the Councilors of the Third, Sixth and Ninth Districts and two Councilors-at-Large shall be elected; and so on in sequence in the years to follow.

Where there is a conflict with the above provisions, as regards the time of expiration of office of any Councilors holding office at the time this Constitution is adopted, then the terms of such Councilors holding office and the terms of the Councilors elected upon the adoption hereof shall cease at such times so that the above provisions may become operative; and any lapses of continuity of office arising through the above provisions shall be filled by the House of Delegates or the Council, as in the case of other vacancies.

When a component county society shall have more than fifteen hundred members, two of the Councilors-at-Large shall be elected from its membership. The district Councilor from each such county, and the two said Councilors-at-Large shall each be elected in different years in calendar sequence.

Section 10.—Powers and Duties of the President-Elect

The President-Elect shall act for the President in his absence or disability, and if the office of President becomes vacant the President-Elect shall then succeed to the Presidency to serve as President for such unexpired term and for the term of one year thereafter.

Section 11.—Election of Council Chairman; Council Vice-Chairman; Secretary-Treasurer; Editor and Associate Editors

The Council, at the organization meeting thereof, shall elect a Chairman, a Vice-Chairman, a Secretary-Treasurer, an Editor; and in its discretion, one or more Associate Editors, each to serve for the term of one year.

Section 12.—Qualifications of Secretary-Treasurer and Editor

No person shall be eligible to the office of Secretary-Treasurer or Editor or Associate Editor who does not hold the degree of Doctor of Medicine, but membership in this Association shall not be a necessary qualification for the offices of Secretary-Treasurer, Editor or Associate Editor.

Section 13.—When Terms of Office of Speaker, Vice-Speaker and Councilors Begin

The terms of office of the Speaker and Vice-Speaker of the House of Delegates (which terms are herein generally stated to be one year) and the terms of office of the Councilors (which terms are herein generally stated to be three years) shall commence immediately upon the adjournment of the last meeting of the House of Delegates of the regular annual session of the Association at which such officers are elected, and shall continue up to the adjournment of the last meeting of the House of Delegates at the annual session of the Association of the year in which the term of office ends.

Section 14.—Officers to Hold Office Until Successors Are Elected and Assume Office

Every officer shall hold office until his successor has been elected and has assumed office either in person or by announcement.

Section 15.[6]—Manner of Election, Term of Office and Duties of the Chairman of the Committee on Public Relations

Shall be as provided for in the By-Laws.

ARTICLE XI.—FUNDS, PROPERTY AND ASSESSMENTS

Section 1.—Annual Assessment of Dues—Other Sources of Funds—Appropriations

Funds shall be raised by equal annual per capita assessment of dues upon the active and associate members, the assessment of dues upon the associate members to be one-half of that upon the active members.

The amount of the assessments shall be fixed by the House of Delegates by a majority vote of the members present and voting.

Funds may also be raised by voluntary contributions, through bequests, legacies, devises and gifts, and from the Association's publications, by special assessments and in any other manner approved by the House of Delegates.

All resolutions providing for appropriations shall be referred to the Council and all appropriations approved by the Council shall be included in the annual budget.

Section 2.—All Funds and Moneys to Be Paid to Secretary-Treasurer and Deposited with Depositary

All funds and moneys received for the Association by any officer or agent thereof shall be promptly paid to the Secretary-Treasurer and by him deposited with a depositary selected as such by the Council.

All depositaries selected by the Council shall be banks or trust companies duly licensed to transact business as such in the State of California.

Section 3.—Membership Interest in Association Property

No person other than an active member in good standing shall have any interest in the property of the Association and the interest of any active member therein shall cease when he ceases to be a member of the Association.

If any active member shall resign or otherwise cease to be an active member of the Association, all of his interest in and to all property of the Association shall cease and such cessation of membership shall operate as a release and assignment to the Association of all the right, title and interest of such member in and to all the property of the Association.

ARTICLE XII.—PUBLICATIONS

Section 1.—Scientific Journal

The Association shall publish and distribute an official journal in the interest of the Association and of its members, devoted to the advancement of medical thought and science, to medical organization, and for the dissemination of medical and public health information.

Section 2.—Annual Directory

The Association may[7] publish an annual directory of members, with such other information as the Council may direct.

Section 3.—Pre-Convention Bulletin

The Association, prior to the annual session, shall print a pre-convention bulletin, which shall contain reports of officers and committees; provided, that the Council shall have the right to delete or modify such reports, and provided further, that committees whose reports have been deleted or modified shall have the right to submit them to the House of Delegates in their original form if the committees so desire.

A copy of the pre-convention bulletin shall be given to each delegate and alternate, on or before registration.

ARTICLE XIII.—INCORPORATION

Section 1.—Incorporation

To aid in carrying out the objects of the Association, the House of Delegates at any meeting of any regular or special session thereof may by a two-thirds vote of the members thereof present and acting, authorize, empower and direct the Council to cause the formation and organization of a non-profit corporation under the laws of the State of California, without capital stock, with such incorporators, name, purposes, objects, principal place of business, term, number of directors and directors to serve for the first year and until their successors are elected and have accepted office, and with such provisions regarding the voting power and property rights and interests of the members of the corporation and such further provisions in the Articles of Incorporation thereof, and with By-Laws and composed of such members representing this Association as the Council shall prescribe, fix and determine. The House of Delegates may at its option in connection with the granting and giving of such authority, power and direction to the Council, prescribe, fix and determine any or all of such matters pertaining to the said corporation, its Articles of Incorporation and any provision thereof, By-Laws and membership, and its action thereon shall bind the Council; and the House of Delegates at any meeting of any regular or special session thereof may by a two-thirds vote of the members thereof present and acting, authorize, empower and direct the Council to grant, assign, transfer, convey and deliver, or cause to be granted, assigned, transferred, conveyed and delivered to the said corporation upon the formation thereof without any consideration therefor, any property, real or pesonal, of the Association, which authorization, power and direction may be given prior or subsequent to the formation and organization of said corporation.

Section 2.[8]

To further aid in carrying out the objects of the Association, the House of Delegates at any meeting at any regular or special session thereof may, by a two-thirds vote of the membership thereof present and acting, authorize, empower and direct the Council to cause the formation and organization of one or more corporations under the laws of the State of California with such incorporators, name, purposes, county where the principal office for the transaction of business is to be located, first directors, the total numbers of shares, the aggregate par value, if any, of all shares, classes of shares, par value of any shares having par value, statement of the provisions, privileges and restrictions granted or imposed upon the respective classes of shares, or if the corporation be formed without capital stock the authorized number and qualifications of its voting and other rights of each class of members and the liability of each and all classes, to dues or assessments, and with such further provisions in the articles of incorporation thereof and with such by-laws as the Council shall prescribe, fix and determine; and the House of Delegates at any meeting of any regular or special session thereof may, by a vote of two-thirds of the members thereof present and acting, authorize, empower and direct the Council to grant, assign, transfer, convey or deliver or cause to be granted, assigned, transferred, conveyed or delivered to any of such corporations upon the formation thereof or to applicants for health and accident or other insurance in or from any of said corporations at or prior to the formation thereof without any consideration therefor, such funds and property, real or personal, of this Association as the House of Delegates shall from time to time authorize or ratify.

ARTICLE XIV.—SEAL

Section 1.—Seal

The Association shall have an Association seal consisting of a circle having on the circumference the words "California Medical Association, Eureka, 1856," with such further emblems, figures and words as the House of Delegates, on recommendation from the Council, shall prescribe.

The power to change the seal shall rest with the House of Delegates.

ARTICLE XV.—AMENDMENTS

Section 1.—Procedure to Amend Constitution

Any member of the House of Delegates at any meeting of any regular annual session thereof may present an amendment or amendments to any article or articles or any section or sections of any article or articles of this Constitution.

Such proposed amendment or amendments shall be in writing and shall be filed with the Secretary and shall thereafter be published at least twice in separate issues of the official journal of this Association prior to the next regular session of the House of Delegates.

At the said next regular session of the House of Delegates, such proposed amendment or amendments shall be submitted to the House of Delegates, for consideration at any meeting of the House of Delegates during that annual session, and if two thirds of the Delegates present and voting vote in favor thereof, the same shall be adopted.

ARTICLE XVI.—REPEAL OF ALL PROVISIONS OF EXISTING CONSTITUTION

Section 1.—Repeal of Existing Constitution

All articles and all sections and all parts of all articles of the existing Constitution are hereby repealed.

BY-LAWS

CHAPTER I.—COMPONENT COUNTY SOCIETIES

Section 1.—Component County Society Charters

The charter of each component county society shall provide that all the provisions of the Constitution and By-Laws of this Association in force at the time of the issuance of such charter, together with all amendments to either thereof thereafter adopted, in so far as the same are applicable, shall be an integral part of the Constitution and By-Laws of the component county society to which the charter is issued and that the terms and provisions thereof shall control and govern such component county society, the officers and members thereof, and that the constitution and by-laws of the component county society shall not be amended in any way to conflict or be inconsistent with the Constitution and By-Laws of this Association. Each charter shall be signed by the President and the Secretary-Treasurer of this Association.

Section 2.—Revocation of Component County Society Charters

The charter of any component county society may be revoked by the House of Delegates if, after the filing with the Secretary-Treasurer of this Association of a written petition or protest signed either by the Chairman of the Council pursuant to resolution adopted by the Council by the affirmative vote of two-thirds of all the members thereof, and after due notice of hearing and after hearing thereof, the House of Delegates by a two-thirds vote of its members decides that the provisions of the Constitution or By-Laws of this Association or of the charter of such society have been breached by such society or that such society has committed acts or conducted itself in conflict with the Constitution, By-Laws or purposes of this Association to such extent as to make such revocation desirable in the best interests of this Association.

Section 3.—(a) Geographical or Specialty Sections

A component society may authorize the formation and existence of branch geographical or specialty sections for scientific investigation and work only, and the members of such geographical sections or specialty sections must be members of such component county society.

(b) Members in Sections to Be Members of Respective Component County Societies

No geographical or specialty section shall be permitted to have any classes of members, which classes in whole or in part include non-members of the component county society of which any such geographical or specialty section is a branch or subdivision; provided that nothing in this section shall be construed as limiting the guest privileges of such nonmembers at meetings of such sections.

Section 4.—Component County Societies Exclusive Judges of Qualifications of Applicants for Membership

Each component county society shall, subject to the minimum requirements for eligibility as provided by the Constitution, determine the qualifications for membership therein, and shall be the sole judge of the qualifications of applicants for such membership.

A member must not practice or claim to practice, support, coöperate with or in any other way endorse any exclusive or sectarian system of medicine. He shall be honorable and ethical in his conduct and shall subscribe to the principles of medical ethics of the American Medical Association and to such as may from time to time be adopted by the California Medical Association, and shall recognize the authorized officers of his component county society and of this Association as the proper authority to interpret any doubtful points in ethics.

Every applicant for membership in a component county society shall fill out and sign in duplicate the application blanks provided by the society, which prescribe the necessary qualifications for membership. One copy of each such application shall be promptly forwarded to the office of this Association.

Section 5.—Component County Society Rosters of Members and of Licensed Physicians in Counties

The secretary of each component county society shall keep a roster of its members and of the nonaffiliated registered physicians of the county, on which shall be shown the full name, address, school and date of graduation, date of license to practice in this State and such other information as may be deemed necessary. In keeping such roster the component county society's secretary shall note and at once notify the Secretary-Treasurer of this Association of any changes in the personnel of the profession, by death, by resignation, or by removal to or from the county, and in making his annual report he shall endeavor to account for every physician who has lived in the county during the year. The secretary of each component county society shall make a monthly report to the Secretary-Treasurer of this Association upon such forms and including such subjects as are herein provided, and as the Council may authorize.

CHAPTER II.—MEMBERSHIP[9]

Section 1.—What Constitutes Membership

The name of a doctor of medicine on the official roster of this Association, after it has been properly reported by the secretary of his component county society, and after the dues or other assessments due this Association shall have been paid by the component county society for each such member according to the class of membership held by each component county society member, shall be prima facie evidence of membership, and of his right to register at the Annual Session.

Section 2.—Termination of Membership

(a) By Expulsion from Component County Societies

Expulsion from any component county society, after due proceedings in accordance with these bylaws, upon becoming final terminates all the rights and privileges in this Association of the member so expelled.

(b) By Failure to Pay Dues

If the annual assessment of dues, payable to this Association by any member of this Association, is not paid on or before April 1 of any year, such member shall automatically lose his membership in this Association as of April 1 of such year. The Council of this Association, in its discretion, upon payment of such unpaid dues, and any other assessments or dues accruing thereafter, may at any time reinstate such member.

(c) By Revocation of Physicians and Surgeon's Certificate

Any active member whose license to practice medicine and surgery in the State of California is revoked shall, upon receipt of written evidence of such revocation by the Secretary of this Association, thereupon cease to be a member of this Association.

(d) Acts and Conduct Subjecting Member to Censure, Suspension or Expulsion by Component County Society

Any active member of a component county society who has been adjudged guilty of a criminal offense involving moral turpitude, or who has been duly adjudged guilty by his society, in accordance with the procedural requirements of these by-laws, of gross misconduct as a physician or a surgeon or of a violation of any of the provisions of the constitution or by-laws or principles of professional conduct of his society or of the principles of medical ethics promulgated from time to time by this Association or by the American Medical Association, shall be subject to censure, suspension or expulsion from his society by such component county society.

(e) Right of Committee on Membership and Organization of This Association to Prefer Charges

If a member of this Association is believed by the Committee on Membership and Organization of this Association to be guilty of conduct justifying censure, suspension or expulsion from his component county society, said committee may prefer written charges in the form and in the manner hereinafter specified with the secretary of the accused member's county society and may, through a member or members thereof, perform all acts that are reasonably necessary and proper in the prosecution of said charges.

Section 3.—Procedure to Be Followed by Component County Societies with Respect to Involuntary Loss of Membership

(a) Disciplinary Procedure for Component County Societies

The procedure to be followed by each component county society with respect to the censure, suspension or expulsion of a member shall be:

(1) Charges; Formal Requirements; A Formal Charge Must First Be Made.—Such charge must be in writing, signed by the accuser, and if made by a person other than a member of the Society must be sworn to before an officer of the State of California authorized to administer oaths. Charges must state the acts or conduct complained of with reasonable particularity.

(2) Charges; Filing; Secretary's Duties; Presentation to Board of Directors (or Grievance Committee).—Charges must be filed with the secretary of the accused member's component society. At the first regular or special meeting of the Board of Directors of such component county society held after charges are filed, the secretary must present said charges to the Board. The Board of Directors shall then or at any adjournment of said meeting, but not more than thirty days after the date of such regular or special meeting, consider the charges, and in its discretion determine whether or not further proceedings shall be conducted. If the Board determines that no further action shall be taken, the charges shall be dismissed.

If a component county society has no board of directors and more than ten members, its members must, at a regular meeting of the society, elect a grievance committee of not less than five (5) active members in good standing; two members shall be designated by the society to serve for a period of one year, two members shall be designated to serve for a period of two years, and one member shall be designated to serve for a period of three years. At the expiration of the terms of office of the respective members of such committee, successors shall be elected in like manner to serve for a period of one year each. Such grievance committee shall exercise all the power and perform all the duties herein conferred upon boards of directors in the manner and within the times herein provided. If a society has less than eleven members, the entire society, exclusive of the accuser and accused, shall constitute the grievance committee. All references herein to board of directors shall be deemed to include boards of councilors and such grievance committees, and component county societies of ten members or less.

(3) Service of Charge Upon Accused.—If the Board of Directors determines that further action, with respect to said charges, shall be taken, the Board must, within fifteen (15) days after such decision, cause a copy of the charges to be served upon the accused by personally delivering a copy thereof to him, or by depositing a copy thereof in the United States mail, registered and addressed to the accused either at his last known office or at his last known residence.

(4) Time and Place for Hearing; Service of Notice Thereof.—The Board of Directors shall, at said meeting at which its decision to proceed is made, fix a time and place for a hearing of said charges. Written notice of the time and place set for the hearing shall be served upon the accused within fifteen (15) days by personal delivery or registered mail as aforesaid.

The time so set for a hearing shall be not less than fifteen (15) days after the accused has been served, as aforesaid, with a copy of the charges and with the notice of the time and place set for the hearing; said hearing must be held within the county in which the accused holds his county society membership. The hearing before the board of directors must actually commence within six months from the date of the filing of written charges. Failure to comply with this requirement shall constitute an automatic dismissal of the charges.

(5) Right of Accused to Answer; Time to Answer; Formal Requirements.—The accused may, not less than five (5) days before the time set for a hearing, answer said charges. The answer shall be in writing and the original and three copies shall be filed with the secretary of the Society; provided, however, that the failure of the accused to answer shall not be deemed to be an admission of the truth of the charges or a waiver of the accused's right to a hearing with respect to said charges.

(6) Rules Governing Hearing; Duties of Referee of Society; Advice As to Procedure Only.—The Board of Directors shall give ample opportunity both to the accuser and the accused to be heard in person, and to present all testimony, evidence, or proofs which the accuser or the accused may deem necessary, provided that the Board may reject all testimony, evidence, or proofs, which in the judgment of the Board are immaterial, irrelevant or unnecessarily repetitious.

The Board in its discretion may be represented by a referee who may, but need not be a member of this Association and who shall be appointed by the Council or Executive Committee of this Association (that is, the California Medical Association) to advise the Board, the officers of the Society, the accuser and the accused, with respect to procedure only. It shall be the duty of said referee to answer all procedural questions submitted by said persons and, on his own initiative, to call attention to any procedural errors.

(7) Record of Proceedings; Shorthand Reporter Discretionary; Duty of Secretary to Preserve Board Records; Right of Accused to Copy.—The secretary shall preserve the original of said charges with a certificate of personal delivery or of mailing of a copy or copies thereof, as the case may be, the original notice of the time and place set for the hearing with a certificate of personal delivery or of mailing of a copy or copies thereof, as the case may be, and the original of the answer filed by any member accused if an answer be filed. At the hearing, the Board of Directors may, in its discretion, and at the expense of the Society, employ a competent shorthand reporter to record and transcribe into typewriting testimony adduced on behalf of the accuser and the accused. If the Board shall decide not to employ a reporter, then the secretary of the Society shall be present and shall keep and prepare a summary of all testimony adduced. The original charges with certificate of service thereof, the original notice of time and place for hearing with certificate of service thereof, the answer or answers, may be filed, if any be filed, all documentary evidence introduced at the hearing, all typewritten transcript of the testimony or the secretary's typewritten summary, and the written decision of the Board of Directors shall constitute the record of the entire proceedings. The secretary shall, upon receipt of a sum sufficient to defray the cost thereof, cause a copy of such record to be transcribed and furnished to the accused. The secretary shall keep such record and, in the event of an appeal to the Council of this Association, shall, upon the request of its secretary, transfer said record to the Council.

(8) Decision of Board; When Must Be Written; Rules Governing Vote of Board.—The Board of Directors, after having given the accuser and the accused member full opportunity to be heard, shall conclude the hearing and shall render its decision in writing not more than thirty (30) days thereafter. Hearing shall include any oral arguments and the filing and consideration of any written briefs. The Board of Directors by a two-thirds affirmative vote of all of the

eligible members of the Board present and voting may exonerate or may censure, suspend or expel the accused member as the facts in its opinion may justify.

The decision of the Board of Directors may be expressed in resolution adopted by said vote. The decision may not contain an opinion and need only be signed by the secretary or the acting secretary of the component county society.

The failure of at least two-thirds of all the members of the Board of Directors present and voting to agree upon the disposition of the charges shall act automatically as a dismissal of the same. No member of the Board of Directors not present at the said hearings for the entire time thereof shall be entitled to vote with respect to the disposition of the charges.

(9) Suspension; Maximum Period; Status of Suspended Member.—If the Board of Directors shall determine to suspend an accused member, the term of such suspension shall be within the discretion of the Board, provided that in no case shall a member be suspended for a period greater than one year. A suspended member shall have no rights or privileges in the Society, provided that at the expiration of the period of suspension such suspended member shall not be reinstated to membership in good standing until he applies for reinstatement and pays all dues accrued during said period of suspension."

(10) (a) Board's Decision; Secretary to Send Copies.—Within ten (10) days after the decision of the Board of Directors, the secretary of the Society shall transmit a copy of the decision to the Board, to the accused member or members and to the secretary of this Association.

(b) Board's Decision Final.—Subject to Appeal.—The action of the Board of Directors of a component society shall be final, subject only to appeal to the Council of the California Medical Association in such cases as are provided in these by-laws.

The decision of the Board of Directors shall not become effective until the expiration of ten days after time during which an appeal may be taken to the Council of this Association. Filing an appeal with the secretary of this Association shall automatically stay the execution of the decision of the Board of Directors of the component county society until written notice of the action of the Council of this Association with respect to appeal has been received by the secretary of the component county society from which the appeal was taken.

(c) Technical Rules of Evidence Not to Govern Disciplinary Hearings.—All hearings with respect to the disposition of charges against a member of a component county society shall be held and conducted in such manner as to ascertain all the facts fairly to the accuser and accused, eliminating all formal or technical rules and requirements which ordinarily pertain to judicial proceedings.

(d) Members Agree That No Cause of Action Shall Accrue.—Any person so charged, censured, suspended, or expelled shall have no claim or cause of action against this Association, a component county society or any member, director, councilor or officer, thereof by reason of such charges, or the hearing or the consideration thereof or censure, suspension or expulsion therefor.

(e) Expelled Members; Right to Apply for Membership; When Accrues.—Any person whose membership has been involuntarily terminated in a component county society by reason of violation of these by-laws may apply for membership after the expiration of one year from the date said membership was terminated, and such application shall be considered in the same manner as a new application for membership.

Section 4.—Procedure for Appeal to Council

A member of a component county society censured, suspended or expelled by his county society may appeal from the action of such component county society to the Council of this Association within the period of two months succeeding the date of such censure, suspension, or expulsion. Appeals shall be in writing and be filed within the said period of two months in the office of the secretary of this Association. Upon the filing of an appeal the secretary shall present it to the first subsequent meeting of the Executive Committee or the Council. Appeals shall be heard by the Council only after reasonable notice of not less than ten (10) days in writing of the time and place of the hearing of the appeal has been given to the appellant member and the president and secretary of the component county society as provided in Section 3 hereof.

Section 5.—Rules Governing Appeals

In hearing appeals, the Council shall review all questions of procedure, and may, in its discretion, review the evidence contained in the record of the original proceedings held before the Board of Directors of the component county society. The Council may make findings of fact contrary to, or in addition to, those made by said Board of Directors. Such findings may be based on the evidence adduced before said Board of Directors, either with or without the taking of evidence by the Council. The Council shall use any lawful means which in its judgment will best and most fairly present all the facts involved. The Council may, for the purpose of making such findings or for other purpose in the interest of justice, take additional evidence of or concerning facts material to the questions involved, or may, for such purpose, appoint a committee of its members or any notary public to act as referees or referee for the taking of such additional evidence.

Such referee or referees shall render a report in writing to the Council, which report shall contain a clear statement of the facts found by the referee or referees from the testimony or evidence adduced.

The Council may affirm, reverse or modify the decision of the Board of Directors or make such other disposition of the proceedings as it may deem proper.

In every case of an appeal the individual councilors and the Council, through a committee thereof, prior to any hearing being held upon the appeal, shall exert all proper efforts at conciliation and compromise.

This Association may be represented by its attorney to advise the Council upon procedural questions only.

The decision of the Council shall be final and bind the appellant member and the component county society.

Section 6.—Registration at Annual Sessions Necessary for Participation Therein

Each member in attendance at the Annual Session shall register, after his right to membership has been verified by reference to the records of this Association. No member shall take part in any of the proceedings of the Annual Session until he has complied with the provisions of this section of the By-Laws.

Section 7.—Component County Society Secretaries to Furnish Data on Applications for Membership

The secretary of each component county society, on forms or blanks supplied by this Association for that purpose, shall notify the Secretary-Treasurer of this Association in writing, as soon as possible, of each application for membership in such component county society, with the name, address, and all other particulars regarding the applicant known to the secretary of such component county society.

Section 8.—Component County Society Membership

(a) Lists to Be Sent to Secretary-Treasurer

It shall be the duty of the secretary of each component county society to furnish the Secretary-Treasurer before the first day of March of each year a list of names and addresses of all members in good standing on the first day of January of each year, and to notify in writing the Secretary-Treasurer of this Association monthly of all changes in membership of the component county society, with corresponding changes of address.

(b) Residence Period Required

No doctor of medicine, otherwise qualified for membership in this Association, shall be elected to membership in a component county society, unless he shall have actually established his residence in the county at least six months prior to the date upon which his application for such membership is acted upon; provided, however, that this time requirement as to residence shall not apply to applicants who seek admission to a component county society by proper transfer credentials from some other component county society of this Association.

Section 9.—(a) Membership Where No Component County Society Exists

Any doctor of medicine residing in a county in which there is no component county society may make application for membership in the component county society most convenient to the county in which he resides, and if otherwise qualified may be elected to membership therein.

(b) Membership in Society of County Other Than That of Residence

Any doctor of medicine living on or near a county line shall be eligible and may apply for and be elected to membership in that component county society most convenient for him to attend, provided that the consent of the component county society of the county in which the doctor resides be first obtained.

(c) Membership Where Major Office and Residence Are in Different Counties

A doctor of medicine, who has his major office for professional practice in one county and resides in another county, has the option of applying for membership in the component county society of either county, provided that both component county societies sanction such action.

Section 10.—Membership as Affected by Transfer of Residence

A member who changes his residence from the county through whose component county society he holds membership in this Association, to another county in which there is a component county society. is eligible to membership in the component county society of his new residence on the presentation of a transfer card, and satisfactory evidence that his dues have been paid in full in the component county society in which he holds membership; provided, however, that no evidence which would disqualify him for membership exists.

He shall forfeit his membership in this Association one year after such change of residence unless he makes proper application for membership in the society of the county to which he has moved.

Any member who has heretofore changed his residence as aforesaid shall have one year after the date of adoption hereof to comply with the provisions of this section.

If a member who so transfers his residence be not elected to membership in the society of the county into which he has moved, he shall have the right to maintain his membership through payment of dues in the society of the county of his former residence if that component county society gives its sanction thereto.

Section 11.—Transfer Cards

When a member in good standing in a component county society moves to another county or other jurisdiction in this State he shall, on request, be given a transfer card, without cost. He must assume such financial obligations as shall be deemed proper by the component county society to which he is transferred, and to which he makes application for membership by transfer.

CHAPTER III.—HOUSE OF DELEGATES

Section 1.—Component County Society Secretaries to Furnish Lists of Delegates and Alternates

The secretary of each component county society in the month of January and in no event later than fifteen days prior to the annual session of the House of Delegates, on form blanks sent in January to each component county society by the Secretary-Treasurer of this Association, shall forward to the Secretary-Treasurer of this Association the names and addresses of the delegates and alternates elected by the component county society to the House of Delegates, and certify to the Secretary-Treasurer of this Association the date of such election and the term for which each delegate and alternate is elected.

Failure to forward said names and addresses within said time to the Secretary-Treasurer shall disqualify said delegates and alternates for said session, unless the Council, for good cause, shall excuse such default. such action of the Council, however, being subject to the approval of the House of Delegates.

Section 2.—Reseating of Delegate in Lieu of Alternate

When an alternate is seated, the Secretary-Treasurer shall record him as having been seated for a specific delegate who is absent. If the delegate so absent later appears, he can be seated in lieu of the alternate, if the alternate announces the presence of the delegate in whose place he is serving, and the House of Delegates sanctions the retirement of the alternate as an acting delegate.

Section 3.—Rights and Duties of Alternate Delegates

The House of Delegates concurring, an alternate shall take the place and perform the duties of any delegate of the delegation from his component county society who is absent from any meeting.

Section 4.—Seating Member in Absence of Delegate and His Alternate

If a delegate be absent, and no alternate be present to take his seat, then, with the sanction of the House of Delegates, some other member of the respective component county society may be seated to fill such vacancy.

Section 5.—Delegates or Alternates Absent from Session Disqualified

Any delegate absent from an annual session to which he has been duly elected, who has not notified the secretary of his component county society at least fifteen days before the convening of said session of his inability to attend, shall be ineligable for re-election as a delegate for the next two years succeeding the expiration of his term of office; provided that nonattendance without such notice may be excused for good cause by the Committee on Credentials.

Secretaries of component county societies shall in writing notify delegates and alternates of their election, and in so doing shall call their attention to the provisions of this by-law.

Section 6.—(a) Appointment of Committee on Credentials and Two Reference Committees

Prior to or at the beginning of an annual session the Speaker of the House of Delegates shall appoint from the members thereof the following committees:

(1) A Committee on Credentials.

(2) A Reference Committee on Reports of Officers and of Standing Committees.

(3) A Reference Committee on Resolutions and on New and Miscellaneous Business.

(b) Membership of Credentials and Reference Committees

Each of the aforesaid committees shall consist of three members, the chairman of each to be designated by the Speaker.

The Speaker, the House concurring, shall refer to these committees such matters as are deemed proper.

The Reference Committees shall present written reports dealing with and making recommendations on all matters submitted to them. The report of each committee shall be read by its chairman first as a whole, and the House of Delegates shall then act and vote upon the report as a whole or section by section, as it may deem best.

(c) Special Committees of House of Delegates

The Speaker, the House of Delegates concurring, shall have the right to appoint special committees for special work. All committees of the House of Delegates shall present their reports to the House of Delegates in writing.

(d) Duties of Credentials Committee

The Secretary of the Association shall supply the Committee on Credentials with the necessary information concerning the membership of the House of Delegates.

The Secretary shall give this committee a list of component county societies, showing the total membership as of November 1 of the preceding year. This committee shall ask each delegate and alternate to present his written credentials, but shall accept the official written list submitted by the secretary of any component county society; provided that such written list be sent to the Secretary of the Association at least fifteen days before the beginning of the annual session.

The committee shall make a written report to the House of Delegates of the delegates and alternates entitled to membership therein.

Section 7.—Delegates to the American Medical Association

The House of Delegates shall elect delegates and alternates to the House of Delegates of the American Medical Association in accordance with the Constitution and By-Laws of that organization.

Section 8.—Special Committees Appointed by the House of Delegates

The House of Delegates shall have authority to appoint committees for special purposes from among members of the Association who may or may not be members of the House of Delegates. Such committees shall report in writing to the House of Delegates; and the members, the House concurring, may participate in the debate on their reports.

Section 9.—Approval of Memorials

The House of Delegates shall approve all memorials and resolutions issued in the name of the Association during an annual session before they shall become effective.

CHAPTER IV.—COUNCIL

Section 1.—Duties of District Councilors

Each District Councilor shall be organizer, peacemaker and censor for his district.

(a) Visitation of Component County Societies; and Report Thereon

He shall visit each county in his district at least once a year for the purpose of organizing component county societies where none exist, of inquiring into the condition of the profession, and of maintaining touch with the activities of the component county societies of his district. He shall in writing make an annual report of this work and of the condition of the profession of each county in his district to the Council, which shall take such action thereon as it may deem best.

(b) Traveling Expenses

The necessary traveling expenses incurred by any Councilor or officer of this Association in performing any duties imposed under the provisions of this Constitution or these By-Laws may be allowed and paid on proper itemized statement, subject to such limitations as the Council may deem wise to adopt; but this shall not be construed to include any expenses incident to attending the Annual Session of the Association.

Section 2.—Mail Ballot

The Chairman of the Council, at any time, may direct the Secretary to submit any urgent matter or question to the members of the Council by mail ballot, the question or proposition being prepared through conference of the Secretary with the Chairman of the Council and the Chairman of the Executive Committee; and the vote of two-thirds of the members upon such question by mail or telegraph shall be binding upon the Council.

Section 3.—Registry

The Secretary-Treasurer, in writing, shall request each Councilor to register his address where he desires all notices to be sent to him by mail or telegram.

Section 4.—Order of Business

At meetings of the Council, business shall be transacted as the Council may determine from time to time by resolution.

The Council shall provide and fix the order of business of the first two meetings of the House of Delegates at each regular annual session, provided that the House of Delegates may change the order of business by a majority vote.[10]

Section 5.—Preparation of Budget—Annual Assessment

The Auditing Committee, prior to December 1 of any year, shall submit to the Executive Committee, for consideration at its December meeting, a budget under which the Association shall work in the fiscal year following the next annual session.

The Executive Committee, after consideration of the Auditing Committee's proposed budget, shall submit the same to the Council, prior to the spring meeting of the Council, with a report of its own containing suggested changes, additions, or comments.

The Council in turn shall consider the two proposed budgets so submitted, and shall then make a final draft of a proposed budget for the Association, to be submitted to the House of Delegates at the next annual session.

The Council shall recommend to the House of Delegates the amount of the annual dues or assessments of each member of the Association.

Section 6.—Committee of Arrangements for Annual Meeting

(a) Appointment and Duties

The Chairman of the Council, subject to the approval of the Council, shall, at least six months before the regular annual session, appoint a Committee on Arrangements for the annual session, one member thereof being designated as the general chairman. This committee shall consist of five members, at least three of whom shall be members of the component county society of the county in which the annual session is to be held.

The Secretary-Treasurer of the Association shall be ex-officio a member of this committee.

This committee shall have charge of all local arrangements not otherwise provided for.

The terms of office of members of this committee shall expire when the succeeding committee of arrangements is appointed.

As the local Committee of Arrangements this committee shall provide suitable meeting places and shall have general charge of all local arrangements. The committee shall have power to appoint local advisory members and subcommittees to aid in its work.

(b) Commercial Exhibit

The Council shall decide what portion of the income from commercial exhibits or other convention services shall go to the local Committee of Arrangements. The location and rules for the commercial exhibits and other accessory annual session activities shall be subject to the approval of the Council.

(c) Local Convention Expenses

The Council shall decide what portion of the local expenses shall be borne by the Association.

(d) Report of Committee of Arrangements

The Committee of Arrangements shall, as soon as possible and not later than two months after the adjournment of the final meeting of the regular annual session, make and file with the Secretary-Treasurer of the Association an itemized, detailed report of all of its receipts and disbursements, and shall remit any moneys due the Association remaining in its possession, to the Secretary-Treasurer.

Section 7.—Offices

The Council shall provide and secure such offices for the Association as may be required to conduct its activities and business properly.

Section 8.—Executive or Field Secretaries or Representatives

The Council may employ one or more Executive or Field Secretaries or Representatives, who need not be physicians nor members of the Association. The duties of such a representative or representatives, if appointed, shall be determined by the Council by resolution.

Section 9.—Legal Counsel

The Council at its annual organization meeting shall appoint one or more legal advisors, giving each such title as may be deemed proper. It shall fix the amount of retainer and other fees. By resolution it shall indicate what duties shall be assigned to each advisor. The Council shall appoint such attorneys-at-law licensed in California at its annual organization meeting.

The Council shall have the right to request the attendance of Counsel of the Association at any meetings at which it might desire his presence and advice, and at such meetings he shall call the attention of the Council to matters in which the legal aspects may be of importance, and shall give such other opinions in special matters as may be requested of him by the Council.

The General Counsel shall present in writing as promptly as the same may be properly prepared, such legal opinions as may be requested by the House of Delegates, the Council or the Executive Committee.

CHAPTER V.—COMMITTEES

Section 1.—Standing Committees

The standing committees of this Association shall be as follows:

(a) A Committee on Scientific Work.
(b) A Committee on Public Policy and Legislation.
(c) A Committee on Publications.
(d) A Committee on Medical Defense.
(e) A Committee on Medical Education and Medical Institutions.
(f) A Committee on Hospitals, Dispensaries, and Clinics.
(g) A Committee on Medical Economics.
(h) A Committee on Health and Public Instruction.
(i) A Committee on Associated Societies and Technical Groups.
(j) A Committee on History and Obituaries.
(k) A Committee on Membership and Organization.
(l) A Committee on Industrial Practice.
(m) A Committee on Post-Graduate Activities.[11]
(n) A Committee on Public Relations.[12]

Section 2.—Standing Committees; How Elected; Terms of Office

Unless otherwise provided in these By-Laws, each of these committees shall consist of three members, each of whom shall serve for a term of three years. One member of each of these committees shall be nominated and elected annually by the Council, by and with the approval of the House of Delegates, provided that at the annual session at which this Constitution is adopted, one member of each of the foregoing committees shall be elected for a term of three years, one member for two years, and one member for one year, their successors to be elected in proper and regular annual sequence thereafter.

Section 3.—Report Procedure for All Committees

Regular standing and special committees of the Association may make investigations and surveys on authorization of the Council or House of Delegates, but all recommendations and reports of all committees (unless expressly otherwise provided in the Constitution or By-Laws) must be submitted only to the Council or House of Delegates. Other than as herein stated no committee is authorized to act for or represent this Association.

Section 4.—Advisory Groups to Standing Committees

To aid it in its work, each committee, if it so desires, shall have the power to appoint an Advisory Group to its committee, consisting of from two to ten members. Such advisory members, if present at a regular committee meeting, shall not have the right to vote.

Section 5.—Officers of Standing Committees[13]

The chairman of each of these committees, except the Committee on Public Relations, shall be nominated and elected annually by the Council, by and with the approval of the House of Delegates. The chairman of the Committee on Public Relations shall be elected by said committee, subject to the approval and confirmation of the Council, and in the event of a failure to elect within sixty days after adjournment of the annual session the Council shall elect said chairman. Each of these committees shall, each year, except as otherwise provided in these by-laws, at its first meeting or official consultation, during or following the annual session, elect its own secretary.

Section 6.—Secretary-Treasurer's Notice to Standing Committees

The Secretary-Treasurer of the Association, within one month after the annual session, shall write the Committee Chairman of the preceding year, to call a meeting for organization and consideration of any business. The Secretary shall also send a copy of this letter to each of the other members of the committee.

Section 7.—Annual Reports of Standing Committees

At least sixty days prior to the annual session, each of these committees shall submit a written report to the Council on its work during the preceding year, the same to be printed in the Pre-convention Bulletin as otherwise provided.

Section 8.—Committee on Scientific Work

The Committee on Scientific Work shall consist of the Secretary-Treasurer, the secretaries of the sections on general surgery and general medicine and three other members to be elected by the Council, each of these three members to serve three years, one member being elected each year. The Secretary-Treasurer shall be chairman.

This committee shall determine the character and scope of the scientific proceedings of the Association for each session, and shall invite the guest speakers,[14] subject to the instructions of the Council.

At least thirty days previous to each annual session it shall prepare and issue a program announcing the order in which papers and discussions shall be presented.

This committee shall have one joint session with the section secretaries, at a time and place to be designated by the Chairman of the Committee, at least forty-five days prior to the annual session, to coördinate more efficiently the various activities of the Association at its annual session. The chairman of the local committee of arrangements shall be invited to attend this meeting.

Section 9.—Committee on Public Policy and Legislation

The Committee on Public Policy and Legislation shall consist of three elected members, and ex-officio, the President and the President-Elect.

The chairman of the committee, and in his absence, the President, shall act as chairman at the joint meetings of this central state group and of auxiliary county groups.

(a) Functions of the Committee

The Committee on Public Policy and Legislation and its auxiliary county groups shall represent the Association in securing and enforcing legislation in the interest of public health and of scientific medicine, subject, however, to the approval of the Council.

(b) County Auxiliary Committees on Public Policy and Legislation

Each component county society shall appoint or elect three of its members as members of its auxiliary Committee on Public Policy and Legislation, designating one member as chairman; and the component county society secretary shall send promptly the names and addresses to the Secretary of this Association.

(c) Work of Auxiliary County Committees

The Committee on Public Policy and Legislation of this Association, with the sanction of the Council, shall formulate the duties of these county auxiliary committees and supply each member with a copy of its suggestions and instructions. The auxiliary committeemen shall be accountable to their component county societies and to the Council of this Association for prompt and continued coöperation with the Committee on Public Policy and Legislation of this Association.

Section 10.—Committee on Publications

The Committee on Publications shall consist of three elected members, and ex-officio the Editor, the Associate Editor or Editors, and the Secretary-Treasurer.

The committee, subject to the instructions and approval of the Council, shall have authority to arrange for the publication and distribution of the Official Journal of the Association and such other publications as the Council or the House of Delegates may direct[15]; and shall consult with the Editors, and with the secretaries of the component county societies to the end that the scientific and organization work of the Association may be presented to the members of the Association in the best possible manner.

Section 11.—Committee on Medical Defense

The Committee on Medical Defense, subject to the approval of the Council, shall prepare plans and establish rules for the protection of the legal rights of members of this Association against whom suits for alleged negligence have been threatened or brought.

It may assist in the defense of any member sued for alleged negligence if the member was in good standing and had complied with the rules of the Council when the service on account of which suit was threatened or brought was rendered—provided that the committee determines that the position of the member merits such action.

Section 12.—Committee on Medical Education and Medical Institutions

The Committee on Medical Education and Medical Institutions shall serve in this state for the Council on Medical Education of the American Medical Association.

It shall keep in touch with the problems pertaining to medical education and to medical and other institutions of training for medicine and the healing art.

Section 13.—Committee on Hospitals, Dispensaries and Clinics

The Committee on Hospitals, Dispensaries and Clinics shall serve in this state for the Council on Hospitals of the American Medical Association.

It shall keep in touch with the problems arising in the fields of work of all types of hospitals, dispensaries and clinics, giving special attention to those activities that are, or tend to become, a menace to the best interests of scientific medicine and of the profession and its members.

Section 14.—Committee on Medical Economics

The Committee on Medical Economics shall investigate matters affecting the economic status of doctors of medicine.

Section 15.—Committee on Health and Public Instruction

The Committee on Health and Public Instruction shall keep in touch with and investigate matters concerned with the public health of the state and shall carry on such activities in the field of public health, and aid in the dissemination of information in relation thereto, as the Council may direct.

Section 16.—Committee on Associated Societies and Technical Groups

The Committee on Associated Societies and Technical Groups, subject to the instructions of the Council, shall endeavor to create proper liaisons between this Association and other state and national medical organizations, as well as with the organizations of related professions, such as dentistry, pharmacy and nursing. It shall also endeavor to bring about a proper understanding with non-medical organizations or groups of technicians and others whose work has a bearing on or is related to the practice of medicine.

Section 17.—Committee on History and Obituaries

The Committee on History and Obituaries shall compile and prepare for the archives and for the publications of the society suitable articles on the history of the Association and statements concerning deceased members. The Editor and the Secretary shall be members of this committee, ex-officio.

Section 18.—Committee on Membership and Organization

The Committee on Membership and Organization, of which the Secretary-Treasurer shall be a member ex-officio, shall each year make a survey of the number of licensed doctors of medicine in the state and shall seek to have the component county societies bring into membership all eligible doctors of medicine in their respective counties; and to that end in the spring of each year, and perhaps oftener, shall send to each component county society a letter, a copy being sent also to each component county society president and secretary, urging each component county society to have a committee on membership appointed for the purpose of making a survey and bringing into affiliation all eligible doctors of medicine.

Section 19.—Committee on Industrial Practice

The Committee on Industrial Practice shall keep in touch with matters and problems peculiarly connected with industrial practice.

Section 20.—Committee on Postgraduate Activities[16]

The Committee on Postgraduate Activities, of which the secretary-treasurer shall be an ex-officio member, shall use its best efforts to promote the postgraduate and clinical courses and instruction among the component county units of the Association.

The supervision of such postgraduate and clinical courses and instruction shall be carried on through the central offices of the Association, the Council being empowered to defray travel expenses of guest speakers and other costs incident to such work to such amount as in the judgment of the Council may be deemed proper. In the development of such postgraduate and clinical courses and instruction, it is stipulated that the component county societies, through their constituted representatives, shall coöperate with the Standing Committee on Postgraduate Activities and shall also arrange to bear a proper proportion of the expense thereof of such amount as may be mutually agreed upon.

(a) Committee on Public Relations[17]

The Committee on Public Relations shall comprise the chairmen of the following committees, viz.: The Committee on Public Policy and Legislation; the Committee on Medical Economics; the Committee on Hospitals, Dispensaries and Clinics; the Committee on Health and Public Instruction; the Committee on Membership and Organization; the Committee on Industrial Practice, and the Cancer Commission; the Committee on Postgraduate Activities; and the President, the President-Elect, and the Secretary.

The Committee shall be responsible to the Council and the House of Delegates for all of its activities.

The Council or the Executive Committee may instruct the Committee on Public Relations, and outline to it certain policies and duties which shall be executed through the Director of Public Relations. In the event of any disagreement between the Committee and the Council or the Executive Committee as to any activity or policy, the decision of the Council, after full discussion and hearing, shall be final.

The Committee shall make recommendations to the Council for approval as to the time, the place, the number of meetings and the budget of the Department of Public Relations, provided that the Secretary shall call the first meeting of the Committee within thirty (30) days following the annual meeting of the Association.

The Director of Public Relations shall be appointed by the Council (after consultation with the Committee on Public Relations) annually at the organization meeting of the Council. He shall serve at the pleasure of the Council and the Committee. He shall act under the supervision and instruction of the chairman of the Committee in such matters as shall be approved and sanctioned by the Committee, and be responsible to the Committee.

The Council shall arrange with the general counsel to give the Committee all legal aid.

The Committee shall annually at its first meeting elect its own chairman, subject to the approval and confirmation of the Council. The secretary of the Association shall be ex-officio secretary. A majority of the Committee shall constitute a quorum.

(b) Department of Public Relations

The Department of Public Relations shall consist of the following component standing and special committees of the Association, viz.: The Committee on Public Policy and Legislation; the Committee on Medical Economics; the Committee on Hospitals, Dispensaries and Clinics; the Committee on Health and Public Instruction; the Committee on Membership and Organization; the Committee on Industrial Practice; the Committee on Postgraduate Activities[18]; and the Cancer Commission.

Section 21.—Publication of Committee Reports in Pre-Convention Bulletin

Reports of the standing and special committees, as approved, deleted or modified by the Council, shall be published in a pre-convention bulletin or in the official journal of the month preceding the date of the annual session of the Association. Such reports must be in the hands of the Secretary-Treasurer at least sixty days in advance of the annual session.

If a committee fails to send in its report in proper time, the name of the committee and the names of its members shall be printed as above indicated, with a statement that the committee failed to send in its report, and the Council, subject to the approval of the House of Delegates, shall be empowered under such conditions to make such changes in the personnel of the committee as in its judgment may be deemed best.

Section 22.—Additional Committees

The House of Delegates and the Council are authorized and empowered to appoint special committees, with special instructions as to work to be undertaken, whenever it is deemed necessary or desirable by either body.

CHAPTER VI.—POWERS AND DUTIES OF OFFICERS

Section 1.—Duties of the President

The President shall preside at all meetings of the Association.

He shall appoint all committees not otherwise provided for; he shall deliver an address at the annual session at such time as may be arranged, and shall perform such other duties as custom and parliamentary usage may require, or as the House of Delegates or the Council may direct.

He shall be the real head of the profession of the state during his term of office, and, as far as practicable, shall visit, by appointment, the various sections of the state and assist the Councilors in building up the component county societies, and in making their work more practical and useful. The Council shall decide what portion of the expenses incurred on his official visits shall be paid by the Association.

He shall be ex-officio a member of all committees of the Association.

Section 2.—Vacancy in Offices of President and President-Elect; How Filled

In case of vacancy in the offices of both President and President-Elect, the chairman of the Council shall act as the Acting President until a President is elected at the next annual session of the House of Delegates.

Section 3.—Duties of the Secretary-Treasurer

(a) Minutes

The Secretary-Treasurer (who may also be referred to as Secretary or Treasurer) shall attend the General Meetings of the Association, the meetings of the House of Delegates, of the Council and of the Executive Committee, and shall keep minutes of their respective proceedings in separate record books.

(b) Custodian of Records

He shall be custodian of all record books and papers belonging to the Association. He shall have the custody of the seal of the Association.

(c) Contracts

He shall countersign all contracts, agreements, conveyances, transfers or other instruments to which the Association is a party, the execution of which has been authorized by the House of Delegates or Council.

(d) Checks

The Secretary-Treasurer shall sign and issue checks or drafts only upon vouchers approved and signed by at least two of the members of the Auditing Committee or as otherwise provided.

(e) Advertisements in Association Publications

The Secretary-Treasurer, subject to instructions by the Council, shall carefully examine, approve, modify or reject all material for advertising in any of the publications of the Association, and shall, in all cases of doubt, refer such proposed advertisements to the Executive Committee or the Council for decision. He shall, with the approval of the Council or the Executive Committee, execute, for the Association, written contracts relating to advertising in the form approved by the Council, subject to instructions by the Council.

(f) Registrar at Annual Sessions

He shall provide for the registration of the members and delegates at the Annual Session.

(g) Index Register of California Medical Licentiates

He shall, with the coöperation of the secretaries of the component county societies, keep a card-index register of all the licensed practitioners of the state by counties, noting the status of each in relation to his component county society; and shall transmit a copy of this list to the American Medical Association, transmitting to its secretary each month a report containing the names of new members and the names of those dropped from the membership roster during the preceding month.

(h) Register of Component County Societies, Their Members and Officers

He shall keep a register of all component county societies, their respective officers, and of all members of the Association, with their addresses, and shall compile an annual directory of the same. He shall print in the January or February issue of the official journal the number of active members of each component county society as of November 1st of the preceding year.

(i) Notices

He shall give all notices required by the Constitution and By-Laws of this Association, or by order of the Council, or of the Executive Committee, or by law.

(j) Correspondence and Notifications to Committees

He shall conduct the official correspondence, promptly notifying members of meetings, officers of their election, and committees of their appointment and duties, as outlined in the motions creating such committees. Such notifications shall be made in writing.

(k) Assistants

He shall employ and dispense with such assistants as may be ordered by the Council. The Council by resolution may outline the scope and duties of special employees acting under the Secretary-Treasurer.

(1) Annual and Other Report Forms

He shall supply all component county societies with the necessary forms for making their annual and other reports to this Association.

(m) Salary

The amount of his salary shall be fixed by the Council.

(n) Bond

He shall give bond in such sum as may be fixed by the Council. The Association shall pay the premium on the said bond.

(o) Duties as Treasurer

He shall as Treasurer demand and receive all funds due the Association, together with bequests and donations, and shall promptly deposit the same in one of the depositaries thereof; and shall keep a proper and accurate record thereof, as well as of all funds disbursed by the Association.

(p) Audits and Reports

He shall subject his accounts to such examination or audit as the House of Delegates or Council may order.

He shall annually render an account of his work, and of the state of the funds in his hands, and make a report on the same and of his work as Secretary-Treasurer to the House of Delegates. He shall in writing also make such other reports as the House of Delegates or Council may request.

(q) Disbursement of Association Moneys

He shall pay out the money of the Association only upon a check or draft as otherwise provided herein.

(r) Other Duties

He shall perform such other duties as the Council or Executive Committee may direct.

Section 4.—Duties and Powers of the Chairman of the Council

The Chairman of the Council shall preside at all meetings of the Council. He shall sign all contracts and agreements, conveyances, transfers or other instruments (other than advertising contracts) to which the Association is a party, the execution of which has been authorized by the House of Delegates or the Council. He shall sign all checks or drafts for the disbursement of funds of the Association. He shall, on behalf of the Council, deliver its annual report to the House of Delegates. He shall perform such other duties as may be imposed upon him by the Constitution or these By-Laws.

Section 5.—Duties of Vice-Chairman of the Council

The Vice-Chairman of the Council, in the absence or inability of the Chairman to act, shall be vested with all the powers and shall perform all the duties of the Chairman.

Section 6.—Duties and Powers of the Speaker

The Speaker of the House of Delegates shall preside at its meetings and shall perform such other duties as parliamentary usage may require. He shall appoint all committees authorized by the House of Delegates, unless otherwise provided.

He shall be ex-officio a member of the Council.

Section 7.—Duties of Vice-Speaker

The Vice-Speaker shall act as Speaker in the absence of or at the request of the Speaker. The Vice-Speaker shall not have ex-officio membership in the Council.

Section 8.—Duties of the Editor

The Editor and Associate Editor or Editors shall compile, edit and have charge of the official journal of the Association and such other publications as the Council or the House of Delegates may instruct him to undertake.[19]

CHAPTER VII.—SESSIONS AND MEETINGS

Section 1.—Addresses at Annual Session

At the General Meetings, at such times as may have been arranged, shall be delivered the annual address of the President and, with the sanction of the Council, such other addresses and reports as may be deemed desirable.

Section 2.—Time Length of Papers

No address or paper, except that of the President, and such other addresses and reports as may be deemed desirable by the Council, shall occupy more than twenty minutes in delivery.

Section 3.—Time Length of Discussions

No member, except by unanimous consent, shall speak more than once in the discussion of any paper nor longer than five minutes at any one time.

This by-law shall be printed on all programs of general and section meetings.

Section 4.—Scientific Papers Property of Association

All papers read before this Association shall be its property.

Each paper, when it has been read, shall be deposited with the secretary of the section, by him to be promptly turned over to the Secretary of the Association.

Section 5.—Scientific Papers Not to Be Published Elsewhere

Authors of papers read before this Association shall not cause them to be published elsewhere except with the consent of the Committee on Publications.

Section 6.—All Meetings of Same Session Shall Be in Same Locality

The general meetings of the Association, the meetings of the House of Delegates, and the meetings of the Scientific Assembly and its sections at any session shall be held in the State of California at the same locality and in buildings as convenient of access, one to the other, as may be possible.

CHAPTER VIII.—ELECTION OF OFFICERS

Section 1.—Time of Election of Officers

The election of officers shall be held at the second meeting of the House of Delegates, at the regular annual session thereof.

Section 2.—Election by Ballot; Number of Votes Necessary

All elections of officers shall be by ballot; provided, that by a two-thirds vote of the members present and acting election by ballot may be waived.

A majority of the votes cast shall be necessary to elect any officer, except delegates and alternates to the American Medical Association.

In case no nominee receives a majority of the votes on the first ballot, the nominee receiving the lowest number of votes shall be dropped and a new ballot taken. This procedure shall be continued until one of the nominees receives a majority of all the votes cast, when he shall be declared elected.

Section 3.—Election of Delegates and Alternates to A. M. A.

In case no nominee for delegate or alternate to the House of Delegates of the American Medical Association receives a majority of the votes cast on the first ballot, the nominee receiving the highest number of votes cast shall be declared elected. In case of a tie vote, the tie shall be determined by lot. A separate election shall be held to fill each vacancy, and an alternate shall be specifically elected for each delegate.

CHAPTER IX.—SCIENTIFIC SECTIONS

Section 1.—(a) Division of Scientific Work

The scientific work of the Association shall be divided into twelve scientific sections, as follows: General Medicine; General Surgery; Pediatrics; Eye, Ear, Nose and Throat; Urology; Anesthesiology; Obstetrics and Gynecology; Radiology; Industrial Medicine and Surgery; Pathology and Bacteriology; Dermatology and Syphilology, and Neuropsychiatry.

(b) Additional Scientific Sections; How Authorized

Additional scientific sections or regrouping of existing scientific sections can through proper resolution be authorized by the House of Delegates.

(c) Rules of Procedure of Scientific Sections

Each scientific section shall adopt rules of procedure for its own better government and work. Its officers shall be responsible for the proper keeping of records of scientific and business meetings.

(d) Officers of Sections

The members of each section shall at the regular annual session of the Association elect a chairman and a secretary of the section to serve for the term of one year.

(e) Program

Each of the sections shall present a scientific program at the annual session of the Association, and its officers shall be responsible for the proper preparation of the same, and for the proper coöperation with other scientific sections during the annual meeting.

CHAPTER X.—FUNDS, PROPERTY AND ASSESSMENTS

Section 1.—Annual Dues and Assessments

(a) When Payable

The annual assessment or dues shall be payable on or before January 1 of the year for which they are levied.

(b) County Secretaries to Collect Dues

The secretary of each component county society shall cause to be collected and shall forward to the office of the Association the dues and assessments for its members.

(c) Record of Fact of Payment of Dues

The record of payment of dues and assessments on file in the office of the Association shall be final as to the fact of payment by a member and as to his right to participate in the business and proceedings of the Association and of the House of Delegates.

Section 2.—Bequests, Legacies, Donations and Gifts

The Association may receive through the Council or for the benefit of the Association through any corporation which may be formed pursuant to Article XIII of the Constitution, such bequests, legacies, donations and gifts as the Council shall deem it proper and suitable to accept.

Section 3.—Funds and Moneys—Deposit and Withdrawal

All funds and moneys of the Association by whomsoever received shall be promptly forwarded to the Secretary-Treasurer of the Association and deposited by him in a depositary of the Association.

No demands or claims against the Association shall be paid and no funds or moneys of the Association withdrawn from any depositary thereof except upon written voucher approved by the signature of at least two members of the Auditing Committee or by a majority vote or written approval of a majority of all the members of the Executive Committee on check or draft signed by any two of the following: The Chairman of the Council; the Vice-Chairman of the Council (only in the absence of the Chairman); Chairman of the Auditing Committee; the Secretary-Treasurer.

Section 4.—Revolving Fund

A revolving fund in such amount as may from time to time be fixed by the Council shall be deposited with the Secretary-Treasurer from which fund immediate cash demands may be paid.

Section 5.—Surplus Funds from Journal and Publications

On authorization therefor by the House of Delegates or the Council, any surplus funds arising from the operation of the official journal or other publications of the Association may be applied and used for any purposes deemed suitable or may be delivered and paid over to any corporation which may be formed pursuant to Article XIII of the Constitution.

CHAPTER XI.—MISCELLANEOUS

Section 1.—Ethics

The principles of medical ethics as promulgated from time to time by the American Medical Association and by the California Medical Association are and shall be the principles of medical ethics of this Association and the component county societies thereof, and shall regulate and govern all members thereof.

Interpretation of ethics about which any controversy may arise or exist shall be submitted to the Council of this Association, and its interpretation and ruling thereon shall be final.

Section 2.—Rules of Order

In the absence of any provision in the Constitution or these By-Laws, all meetings of the Association, of the House of Delegates, of the Council, and of committees shall be governed by the parliamentary rules and usages contained in the current edition of Roberts' "Rules of Order."

CHAPTER XII.—AMENDMENTS *

Section 1.—Amendments—Vote and Procedure

These By-Laws may be amended by the House of Delegates at any meeting of any session thereof by the affirmative vote of at least two-thirds of the qualified members thereof present and acting; provided, that any proposed amendment has been submitted in writing to the House of Delegates at least twenty-four hours previous to being voted upon.

---

* See page 200 for key number references to amendments included in this "Second Printing Revision."

CHAPTER XIII.—CORPORATIONS[20]

To further aid in carrying out the objects of the Association the House of Delegates, at any meeting at any regular or special session thereof, may by a two-thirds vote of the membership thereof present and acting, authorize, empower and direct the Council to cause the formation and organization of one or more corporations under the laws of the State of California with such incorporators, name, purposes, county where the principal office for the transaction of business is to be located, first directors, the total number of shares, classes of shares, par value of any shares having par value, statement of the provisions, privileges and restrictions granted or imposed upon the respective classes of shares, or if the corporation be formed without capital stock, the authorized number and qualifications of its members, the different classes of members, if any, the property, voting and other rights of each class of members and the liability of each and all classes, to dues or assessments, and with such further provisions in the articles of incorporation thereof and with such by-laws as the Council shall prescribe, fix and determine; and the House of Delegates at any meeting of any regular or special session thereof may by a vote of two-thirds of the members thereof present and acting, authorize, empower and direct the Council to grant, assign, transfer, convey or delivery or cause to be granted, assigned, transferred, conveyed or delivered to any of such corporations upon the formation thereof or to applicants for health and accident or other insurance in or from any of said corporations at or prior to the formation thereof without any consideration therefor, such funds and property, real or personal, of this Association as the House of Delegates shall from time to time authorize or ratify.

CHAPTER XIV.[21]—REPEAL OF ALL EXISTING BY-LAWS

Section 1.—Repeal of Existing By-Laws

All chapters and all sections and parts of all chapters of the existing By-Laws of this Association are hereby repealed.

KEY TO AMENDMENTS

Key numbers in the text of this edition of the Constitution and By-Laws of the California Medical Association give the references to minutes of the House of Delegates as printed in the official journal, "California and Western Medicine." Key number references follow:

1. By typographical error in first printing of Constitution and By-Laws in 1929, San Bernardino County was included as part of Councilor District No. 2.
2. 1933—Art. VII, Sec. 1, California and West. Med., June, 1933, p. 457.
3. 1933—Art. VII, Sec. 8, California and West. Med., June, 1933, p. 457.
4. 1934—Art. X, Sec. 1, California and West. Med., June, 1934, p. 437.
5. 1934—Art. X, Sec. 4, California and West. Med., June, 1934, p. 437.
6. 1934—Art. X, Sec. 15, California and West. Med., June, 1933, p. 457.
7. 1934—Art. XII, Sec. 2, California and West. Med., June, 1933, p. 457.
8. 1935—Chapter XIII, Sec. 2, California and West. Med., July, 1935, p. 59.
9. 1936—Chapter II (entire chapter), California and West. Med., July, 1936, p. 80.
10. 1932—Chapter IV, Sec. 4, California and West. Med., June, 1932, p. 422.
11. 1935—Chapter V, Sec. 1, California and West. Med., July, 1935, p. 74.
12. 1933—Chapter V, Sec. 1, California and West. Med., June, 1933, p. 463.
13. 1933—Chapter V, Sec: 5, California and West. Med., June, 1933, p. 463.
14. 1932—Chapter V, Sec. 8, California and West. Med., June, 1932, p. 422.
15. 1932—Chapter V, Sec. 10, California and West. Med., June, 1932, p. 422.
16. 1935—Chapter V, Sec. 20, California and West. Med., July, 1935, p. 74.
17. 1933—Chapter V, Sec. 20A, California and West. Med., June, 1933, p. 463.
18. 1936—Chapter V, Sec. 20B, California and West. Med., July, 1936, p. 84.
19. 1932—Chapter VI, Sec. 8, California and West. Med., June, 1932, p. 422.
20. 1934—Chapter XIII, Sec. 1, California and West. Med., July, 1934, p. 440.
21. In the first printing in 1929, the title then given was a typographical error.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

COUNTY HOSPITALS

In commenting on socio-economists, the secretary of the Kansas State Medical Society employs an odd simile. We are employing it in this comment.

I suppose a snake swallows a toad without personal animosity. One with a kindly disposition and a good imagination may even believe that he does it in a spirit of helpfulness—it surely is some protection to the swallowed batrachian—but the toad finds it a disquieting, even a terrifying experience. He just "doesn't want to." Now supervisors and farm bureaus seem bent on making a snake and toad union with the county hospital and medical services. We admit we are alarmed and opposed to such deglutition.

We are opposed because:

1. It will cause hospital and medical services to become a political football.

2. Because county hospitals will practice medicine which the law states cannot be done by organizations or corporations.

3. Because there will be no free choice of physician.

4. Because it will destroy the so essential patient-physician confidential relation.

5. Because it will make physicians public servants under lay control and dominance.

6. Because it will lower the quality of medical care.

7. Because it will cause a tremendous increase in taxes by millions of dollars.

8. Because it will eventually destroy our present methods of rendering medical care that has been the important factor in producing our present morbidity and mortality rates.

9. Because medical care is an individual service and cannot be rendered efficiently under lay and political supervision. Doctors by reason of special training are alone able to administer medical care.

10. Because it injects politics and political invasion into the sick chamber of American homes.

For these, and still many other reasons, do we oppose any and all efforts to open up the county hospitals to others than the indigent or those whom the law classifies as wards of a county. Every physician should unceasingly work to defeat this political proposal. Inform your friends and patients. Remember Mr. Siemon's address to the House of Delegates at Coronado, and learn what happened in Kern County. Proponents are spreading their arguments and misinformation. Refute these at every opportunity. The movement should be discouraged persistently.

* * *

FINGER PRINTS

The movement seeking to secure a finger print record of all persons merits endorsement and coöperation of all our members. One need but mention the following advantages:

1. Identification of unconscious patients, or those injured in accidents or catastrophies.

2. Identification of the dead who may have been so mutilated as to be unidentifiable.

3. Identification of lost children.

4. Identification of individuals suddenly bereft of sanity and mental faculties.

5. Personal identification by authorities.

---

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

These are certainly valid reasons why everyone should arrange to go to their nearest police station or to the Federal Bureau of Investigation and be finger-printed. Many have gone to unknown graves and relatives have never been able to trace them because when death overtook them in a distant place it was impossible to identify the individual. Every major disaster, fire, cyclone, wreck or earthquake has left its toll of unidentified dead or severely injured. "Everyone finger-printed" is a slogan all will do well to heed.

* * *

FORESTRY MEDICAL SERVICE

The following bulletin has been sent to members in the Forestry Service:

FORESTRY MEDICAL SERVICE
CALIFORNIA MEDICAL ASSOCIATION
450 Sutter Street
San Francisco, California

June 15, 1936.

To Members:

IMPORTANT

Several months ago the Conservation Committee of the California State Chamber of Commerce requested the California Medical Association to take over, supervise and direct the *California Forestry Medical Corps.* The California Medical Association accepted this activity. At that time the corps had as its chief medical officer a Los Angeles ostopathic physician and there were some fifty osteopaths in the corps.

In due time the Conservation Committee and the executive officer cancelled the appointment and appointed the secretary of the California Medical Association as chief medical officer. Steps were taken to enroll corps members from lists recommended by county medical societies. This work was just about completed when, on May 26, 1936, we learned that a group of osteopaths with the former chief medical officer had, on their own initiative, secured articles of incorporation and purloined the name of *"California Forestry Medical Corps."*

We also learned of other unapproved activities and that car plates and badges were being used by many Hollywood non-medical persons.

In conference with representatives of the California State Chamber of Commerce and the Forestry Departments, it was decided to reorganize the corps and change the name to FORESTRY MEDICAL SERVICE OF THE CALIFORNIA MEDICAL ASSOCIATION.

REORGANIZATION PLANS

1. Change of name.
2. Reënlistment of members.
3. Change of badge and car plates.

This is being accomplished. You will find new application blank enclosed. Also order blank for new badge and automobile plates. *Please return promptly.* As the fire season is at hand, it is extremely important that our reorganization be perfected without delay. Kindly give this your immediate attention.

Yours sincerely,
FREDERICK C. WARNSHUIS, M. D.,
Chief Medical Officer.

We have since learned that some members have enrolled in the old corps. Resignation is in order. Under date of June 10 the former chief medical officer sent out a circular letter. This and all similar communications should be ignored, as the Forestry Medical Service of the California Medical Association is the only official organization and is so recognized by the Forestry and State officials.

* * *

MINUTES OF THE MEETING OF THE COMMITTEE ON PUBLIC RELATIONS

1. **Call to Order.**—The meeting of the Committee on Public Relations was called to order by Chairman Dukes in the Sir Francis Drake Hotel in San Francisco on June 20 with the following members present: Doctors C. G. Toland, E. M. Pallette, Morton R. Gibbons, F. B. Clarke, Howard Morrow, Daniel Crosby, William W. Roblee, Mr. Hartley Peart, Chairman Dukes and Director Warnshuis.

2. **Public Health Institutes.**—The Director requested questions as to the program and itinerary for public health institutes following the closing of the San Diego Exposition.

On motion of Doctor Toland, seconded by Doctor Clarke, the director was instructed to conduct the public health institutes as long as funds are available to defray the expenses thereof. Carried.

3. **Intercoast Hospitalization Insurance Association.**—Dr. Frank A. MacDonald and Mr. R. D. Brisbane of the Intercoast Hospitalization Insurance Association were guests at the meeting. They explained the manner in which services are given to their members and asked that sanction of their association be given by the Public Relations Committee. Doctor MacDonald said that, although x-ray and clinical services are now included in their policies, they would be perfectly willing to pay the patient direct for x-ray and clinical services and they, in turn, would pay the doctor.

A general discussion ensued.

It was moved by Doctor Gibbons, seconded by Doctor Crosby that the Committee on Public Relations request the Council to hold a special meeting for the purpose of discussing the problems that confront the committee in the evaluation of insurance plans in order that a uniform policy may be determined. Carried.

4. **Public Health Lectures.**—After discussion, Chairman Dukes requested each member of the Committee on Public Relations to write a fifteen or twenty minute lecture. These lectures will then be edited by the committee and made available as material for speakers who are to appear before public health meetings.

5. **Radio Talks.**—Doctor Clarke discussed the possibility of building up a large radio audience and suggested that each county society launch a campaign and use the following methods:

(1) Advertising in local papers in the radio section, the time and title of each lecture and obtain special listing of these programs.

(2) Get various companies to sponsor a program—like milk companies—and the speaker in the course of the lecture could mention the name of the product.

(3) Enlist the support of hospitals. Have cards printed and passed out to patients.

It was moved by Doctor Crosby and seconded by Doctor Graves that Doctor Clarke send a letter to Doctor Warnshuis, the director, embodying his suggestions and the director then write to each county society enlisting their aid.

The meeting adjourned at 4 p. m.

COMPONENT COUNTY MEDICAL SOCIETIES

LASSEN-PLUMAS-MODOC COUNTY

The members of the county medical society were guests of Dr. Fred J. Davis at his home in Westwood on the evening of June 13, 1936. Visitors present were: Dr. Lewis Michelson of San Francisco, Dr. H. G. Levin of Westwood, Dr. Wilbur Batson of Greenville. The meeting was preceded by a dinner given by Mrs. Davis to the members of the society and the Woman's Auxiliary.

The scientific meeting which followed the dinner was very interesting. Doctor Michelson presented a paper on *Urology in General Medicine,* illustrated by lantern slides. Doctor Michelson has the thanks of our society for a very instructive and interesting paper. Following this the annual election of officers was held. The following officers were elected for the ensuing year: President, C. I. Burnett, Susanville; secretary, Fred J. Davis, Jr., Westwood. There being no further business, the meeting adjourned.

C. I. BURNETT, *Secretary.*

⁂

PLACER COUNTY

The Placer County Medical Society met at the Freeman Hotel, Auburn, Saturday evening, July 11, being called to order by President Louis E. Jones. In addition to President Jones there were the following members and visitors present: Members, Doctors Russell, Atkinson, Peers, Mackay, L. B. Barnes and Briner. Visitor, Dr. Harold L. Karo, of Grass Valley.

The following physicians were elected to membership: Dr. Harold L. Karo, 128 Neal Street, Grass Valley, and Dr. Daniel L. Hirsch, Thomas Building, Grass Valley.

Correspondence from Secretary Warnshuis' office was read and the following resolution, on motion by Doctor Briner, seconded by Doctor Atkinson, was unanimously adopted:

"The procedure to be followed by this society with respect to censure, suspension or termination of membership of a member of this society shall be the procedure now or hereafter contained or provided for by the by-laws of the California Medical Association, as now existing, and as the same may hereinafter be amended. This section shall supersede any of the provisions of these by-laws in conflict therewith."

Two letters from Mr. Ben H. Read, executive secretary of the Public Health League of California, were read and appropriate action taken. Dr. J. A. Russell, of Auburn, was appointed as a Committee of One to contact the various candidates for office.

Doctor Atkinson and Doctor Briner brought up the matter of the exhibition, before the society, of motion pictures on various surgical and medical subjects. It was unanimously agreed that such motion pictures would be interesting and instructive. Dr. R. C. Atkinson was appointed associate secretary and instructed to make the necessary arrangements for presenting such motion pictures at subsequent meetings.

Under the head of Reports of Cases, Dr. Louis E. Jones reported a case of a patient who had had drainage of the left antrum in San Francisco on July 3. On July 4 he came to Roseville and, because of headache, malaise and other symptoms of toxemia, consulted Doctor Jones. July 5, on the appearance of a rash, it was determined that the patient had scarlet fever. He died July 9 of generalized septicemia. Doctor Jones believes that there might have been a relationship between the antrum opening and the development of the septicemia.

Dr. R. C. Atkinson reported a case of relapsing fever. Because of its special interest that portion of the minutes reporting this case will be given in the Case Report column in this issue.*

Adjournment.

Robert A. Peers, *Secretary.*

* * *

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was called to order by the president, Dr. Frank MacDonald, on May 19, 1936, at the auditorium on Twenty-ninth and L streets.

The minutes of the last meeting were read and approved. There were no case reports. Eighty members and guests were present.

Dr. Robert A. Peers of Colfax, president of the California Medical Association, gave a brief résumé of his work as president for the past year and stated that he had visited each of the forty county societies in the state during his term of office. He spoke most warmly of the coöperation and enthusiasm of the officers and members of the component societies who helped to make these visits a success. He stressed the fact that the California Medical Association has a most democratic form of government and that its members comprise 83 per cent of the desirable practicing physicians of California. In closing, Doctor Peers stated that the members of the Association do not take the opportunity often enough to express their views on matters of common interest to their delegates and Councilors. He advised the members to read California and Western Medicine, and thus keep abreast of the problems the profession is facing in these changing times, and stated that critical skepticism is a healthy attribute for a physician to possess.

Mr. Hartley Peart, general counsel of the California Medical Association, the next speaker, cited three interesting cases affecting medical practice in California. The first relating to the corporate practice of medicine in which the District Court of Appeal reversed the decision of the Superior Court which had granted a mandamus action brought by the Pacific Employers' Insurance Company against the State Insurance Commission. The second case related to the suit brought against the supervisors of Kern County to restrain them from admitting pay patients to county hospitals. The fourth District Court of Appeal of San Bernardino County rendered a decision favorable to the California Medical Association, although it did not settle all points raised in the briefs submitted by counsel of the California Medical Association. The third case was brought to restrain nurses and hospitals from the practice of anesthesiology. This case was lost, and when appealed by the California Medical Association the Supreme Court reaffirmed the judgment in favor of hospitals and nurses. Mr. Peart stated that a new disciplinary code has been worked out by the Committee on Legislation which he hopes will be adopted as a by-law of the California Medical Association at the convention at Coronado. In closing, Mr. Peart advised the members to take a direct interest in politics, since every eighth or tenth measure introduced in the legislature affects the medical profession directly.

The third speaker of the evening, Alson R. Kilgore, M. D., president of the Northern District of the Public Health League of California, dwelt on the work and program of his organization to impress the meeting with the importance of supporting that program through membership. He stated that at the last legislative session for 1935, of seventeen bills opposed by physicians and dentists, none passed, and of fifty-two measures favored by the two professions, all but two were passed. The ultimate fate of these bills was determined in large measure by the Public Health League. The membership of the Public Health League provided concerted effective action to oppose measures inimical to the welfare of medicine and dentistry and he urged all members of the society to promote their own welfare by affiliating with the League.

Dr. Glenn F. Cushsman, secretary of the Public Health League of California, spoke briefly about the measure fostered by the supervisors of Kern County which will probably appear on the ballot this year if the necessary 186,000 signatures are obtained to qualify it. The Public Health League will do its utmost to defeat this initiative which would result in the opening of county hospitals to all citizens and incidently further the political ambitions of the supervisors.

The application of Dr. Edgar Haag for membership in the society was read for the first time. Doctors Lung Fung, Glenn E. Millar and Leslie A. Runyan were unanimously elected to membership in the society.

The report of the Board of Directors was read.

Dr. Orrin Cook spoke on the contemplated tuberculin testing of high school students in Sacramento and stated that this work would be paid for by the Sacramento Tuberculosis Association. He asked that any physician wishing to do this work communicate with him. Doctor Peers suggested that the teachers should also be included in this examination.

Dr. Bert Howard spoke on establisihng a psychopathic ward in Sacramento as an aid in limiting the admissions to state hospitals for the insane, and the following motion was passed:

"That the Sacramento Society for Medical Improvement go on record as approving such changes in the care and custody of the mentally sick as shall conform to the intent and purpose of the Lunacy Law of the State of California."

There being no further business, the meeting adjourned.

* * *

A regular meeting of the Sacramento Society for Medical Improvement was called to order by the president, Dr. Frank A. MacDonald, in the auditorium at Twenty-ninth and L streets on June 16, 1936.

There were forty-three members present. The minutes of the last meeting were read and approved. There were no case reports.

A symposium on *Tumors of the Breast* was presented by Doctors Guttman, Rulison and Orrin Cook.

Doctor Guttman presented a *Classification of Breast Tumors* together with microphotographs of sections of breast tissue and photographs of gross specimens. He grouped breast tumors under two main heads: 1. Benign, including fibroma, papilloma and duct papilloma which represent 15 per cent of all cases. 2. Malignant, classified into carcinoma and Paget's which represent 80 per cent of breast tumors. He stated that 95 per cent of all breast tumors can be diagnosed grossly by pathologists at the operating table as to malignancy. He also stated that microscopic examinations, to be exact, must be done in serial sections for accurate diagnosis in duct papilomas.

---

* See page 172 for report.

Doctor Rulison spoke on the *Treatment of Breast Malignancy*, using as a basis for his discussion the statistics of Hutchinson, a Glasgow radiologist. Hutchinson's figures indicated that when surgery alone was resorted to, the percentage of three-year cures was only 3 per cent better at the present time than in 1914. When surgery plus x-ray was used the statistics show a 16 per cent improvement in favor of the patient. X-rays alone during the first introduction of this new weapon showed a 49.4 per cent in three-year cures and 54 per cent in five-year cures. These statistics refer to early cases only. Examination of statistics of cases from the years 1922 to 1932 treated with x-ray alone show the results to be 23 per cent better than obtained by surgery plus x-ray and 40 per cent better than by surgery alone. Hutchinson's conclusions are that surgery is no longer the treatment of choice for breast malignancy. Radiations combined with surgery produce better results than surgery alone. X-ray therapy when properly employed produces results surpassing those of any other procedure. In closing the speaker said he would continue to operate on what he felt were early cases of breast malignancy but in view of Hutchinson's critical analysis more frequent use of x-rays will be resorted to in the future without surgery.

Dr. Orrin Cook opened the x-ray discussion by mentioning the value of taking x-rays of the breast tissue itself by soft tissue technique and stated this may be helpful in deciding whether the case under consideration is malignant or not. He mentioned four factors determining regression of the tumor: 1. Radiosensitivity compared to normal surrounding tissues must be great enough to permit adequate dose to be given. 2. Presence or absence of metastasis. 3. Amount of area involved. 4. Accessibility to treatment. He enumerated four processes by which the cancer cells disappear: 1. Coagulation necrosis. 2. Fragmentation of nucleus. 3. Monster-daughter cells evolved which cannot reproduce. The tumor bed has resistance built up against spread of the process. This resistance is higher if not disturbed by the knife. Better results are obtained by small doses at frequent intervals which will destroy the cancer cells during the period of mitosis when they are most vulnerable. It is well to keep in mind the possibility of radiation fibrosis of the lung.

In the discussion that followed Doctor Zimmerman advocated a modified Coutard treatment of breast tumors with an interval of two months between surgery and radiation.

Doctor Lawson mentioned the value of sterilization of the patient by x-ray if she has not yet passed the menapause and stated that there is no appreciable advantage using over 200,000 volts in treatment.

Doctor Graham quoted Portmann's statistics of many surgeons to show that x-ray plus surgery had a higher survival than surgery alone.

The application of Dr. Edgar Haag was read for the second time and he was unanimously elected to membership in the society.

It was moved, seconded and passed that the society ratify the names of Doctors G. Wilson and Frank MacDonald for choice of representatives of the society on the County Health and Welfare Board.

There being no further business, the meeting adjourned.

Norris R. Jones, *Secretary*.

⁂

SAN BERNARDINO COUNTY

The San Bernardino County Medical Society met at the San Bernardino County Charity Hospital on Tuesday, June 2, 1936. The meeting was called to order by the president at 8:15 p. m. About thirty-five members and guests were present. The minutes of the previous meeting were read and approved.

Dr. H. M. Walton reported on the recent meeting of the House of Delegates held during the annual session of the California Medical Association in Coronado. Doctor Walton discussed the new county hospital problems which come up at the November election and urged membership in the Public Health League.

Dr. C. L. Emmons reported that the California Medical Association had decided not to act on medical protective insurance for another year, as long as policies were available with reliable companies.

Doctor Emmons moved that the society send a vote of thanks to Mr. H. P. Thoreson, who recently resigned as county SERA director, for his efforts in behalf of the medical society while in office. The motion was carried.

Doctor Clough stated that the society had shown its appreciation to Mr. Thoreson on numerous occasions in the past and that, since Mr. Thoreson had recently announced his candidacy for Congress, he felt it unwise for a non-political body such as the county medical society to do anything at this time which might be construed to mean a political endorsement, and therefore moved that the motion before the society be laid on the table. The motion was seconded, and after more discussion, passed.

There being no further business, the program of the evening was then given, as follows: *The Friedman Test in the Abnormal States of Pregnancy*, George D. Maner, M. D., Los Angeles; *The Friedman Test in the Early Diagnosis of Chorionepithelioma*, E. M. Lazard, M. D., Los Angeles. Discussion of both papers was started by Dr. Delbert Williams.

A. E. Varden, *Secretary*.

⁂

SAN MATEO COUNTY

A special meeting of the San Mateo County Medical Society was held June 24, 1936, in the staff room of Mills Memorial Hospital at 8 p. m., the secretary presiding.

Dr. Hartzell Ray, delegate to the annual meeting of the California Medical Association, presented an illuminating report of the activities carried out by the House of Delegates at the annual session in Coronado. The society gave Doctor Ray a vote of thanks for his report.

The chairman then mentioned the names of Mr. Higgins and Mr. Call, candidates for the Assembly from this district, and read part of a letter he had received from Mr. Call. From all the available information it was apparent that both candidates were well qualified and had both promised to support public health policies in the state legislature. The county society declined to support any candidate for any office feeling that in the present instance at least it was a matter of individual preference on the part of physicians.

Next, the matter of immunization of school children was brought up for discussion. The chairman expressed the feeling that immunization should be under the control of and in the hands of the private physician even in those cases where patients could not afford to pay the usual fee for these procedures. The fact was emphasized that immunization of non-indigent patients properly belongs in the hands of the family physician, and that it would be to his ultimate best interests to provide such service for those unable to pay the standard fee even where indigents could do no more than pay for the cost of materials. Doctor Murphy discussed the plan in operation in Detroit, where all such work is backed by the county medical society and performed by the individual physician. Doctor Shaghoian mentioned a special problem which exists in Daly City, where a San Francisco physician is employed by lay groups to not only immunize the school children of Daly City but also to supervise the well baby clinic. In connection with this the secretary was directed to investigate the circumstances of the case. After considerable discussion, all of which favored placing immunization in the hands of the family physician, it was decided to appoint a committee to prepare literature to be distributed to parents of school children through the schools announcing that the immunization and vaccination of school children was under the control of the county medical society and would be performed by the family physician at a set rate for those patients able to pay, with a sliding scale to provide such services for patients unable to pay the standard rate. Accordingly the chairman appointed the following Committee on Immunization and Vaccination of School Children: Doctors William Murphy, Hartzell Ray and Wade Macomber.

In connection with the proposed initiative for opening county hospitals to the public, which will be on the ballot at the November election, Dr. Otis Allen Sharpe spoke of the work being done by the Public Health League to fight this initiative and requested coöperation of county society members with the Public Health League in this matter. The chairman announced that a legislative committee consisting of Doctors Day, Benninghoven and Bridgman was working on this problem from the standpoint of the county medical society.

J. Garwood Bridgman, *Secretary.*

CHANGES IN MEMBERSHIP

New Members (17)

Los Angeles County.—John G. Amthor, George A. Bendlage, Potter Bowman, J. Clough Frudenfeld, Frances Holmes, Tracy O. Powell, Ralph Rhind.

Monterey County.—Winton F. Swengel.

Orange County.—John P. Davis, Stella K. Davis, Chad M. Harwood, Kirtland G. Parks.

Riverside County.—James Farrage.

San Joaquin County.—Leo D. Smith.

San Mateo County.—Charles C. Gans, John P. Russel.

Tehama County.—Otho T. Wood.

In Memoriam

Fisher, Charles Albert. Died at Los Angeles, June 20, 1936, age 58. Graduate of the College of Physicians and Surgeons, Los Angeles, 1913, and licensed in California the same year. Doctor Fisher was a member of the Los Angeles County Medical Association, the California Medical Association and the American Medical Association.

+

Latta, Samuel E. Died at Stockton, June 13, 1936, age 74. Graduate of Rush Medical College, Chicago, 1884. Licensed in California in 1886. Doctor Latta was a member of the San Joaquin County Medical Society, the California Medical Association, and the American Medical Association.

+

March, William Bright. Died at Burson, June 23, 1936, age 77. Graduate of the Eclectic Medical College, Cincinnati, 1884, and licensed in California the same year. Doctor March was a retired member of the San Joaquin County Medical Society, the California Medical Association, and the American Medical Association.

+

Richter, Clemens Max. Died at San Francisco, May 19, 1936, age 88. Graduate of the Universitat Leipzig Medizinische Fakultät, Saxony, Germany, 1872. Licensed in California in 1876. Doctor Richter was a retired member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Rothschild, Max Landower. Died at Napa, July 11, 1936, age 65. Graduate of the Universitat Heidelberg Medizinische Fakultät, Baden, Germany. Licensed in California in 1897. Doctor Rothschild was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

THE WOMEN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION[†]

MRS. ANDREW J. THORNTON..............................President
MRS. ROBERT M. FURLONG..............................Editor and Chairman of Publicity

STATE AUXILIARY NEWS

Minutes of the Seventh Annual Meeting of the Woman's Auxiliary to the California Medical Association

Tuesday, May 26, 1936.—The first session of the seventh annual meeting of the Woman's Auxiliary to the California Medical Association convened at 9:30 a. m. in the Coronado Yacht Club, Coronado, California, Tuesday, May 26, 1936, with Mrs. Thomas J. Clark, president, presiding. The invocation was offered by Reverend Willis S. Goldsmith.

Mrs. Clark then introduced Mrs. Elliot Colby, convention chairman, who outlined the activities of the plans for the visitors.

The address of welcome was given by Mrs. Emil C. Black of San Diego County.

The response was given by Mrs. J. C. Geiger of San Francisco County.

Mrs. J. C. Condit of Alameda County gave a brief and beautiful service in memory of those members who passed away during the past year. There were nine, the record of which will appear in the "In Memoriam" book of the State Auxiliary.

Mrs. C. Kelly Canelo of Santa Clara County, the recording secretary, called the roll for the county Auxiliaries. Those present were:

	Delegates	Alternates
Alameda	7	5
Contra Costa	2	0
Fresno	5	3
Kern	3	1
Lassen-Plumas	1	0
Los Angeles	11	12
Marin	1	0
Orange	4	3
Sacramento	3	3
San Diego	5	5
San Francisco	5	5
San Joaquin	3	3
Santa Barbara	2	0
Santa Clara	5	4
Riverside	3	3

Mrs. Elliot Colby, convention chairman, gave a written report.

Mrs. C. C. Tanner of San Diego, acting as chairman for Mrs. D. E. Froehlich, chairman of Credentials and Registration, reported thirty-seven delegates, twenty-four alternates, sixteen board members, 108 members, thirteen guests.

Mrs. A. E. Anderson read the report on the Convention Rules, which were approved, as follows:

1. Delegates are requested to be in their seats five minutes before the time of opening of meeting.
2. All visitors are welcome to general sessions.
3. Accredited delegates and members of the board only have the privilege of voting.
4. Debate open to delegates, alternates, state board members, members at large.
5. No newspaper reporters are admitted to sessions.
6. Delegates must be seated by districts.
7. Alternates shall not be seated with delegates except when representing absent delegates, when the alternate must wear the badge of the delegate.

[†] As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

8. Members must obtain the floor, giving name and name of Auxiliary, before making a motion or speaking from the floor.

9. No member of the convention shall speak in debate more than twice on the same subject, or longer than three minutes, without the consent of the assembly.

10. That all may enjoy the convention, those present are asked to refrain from whispering; pages will pass notes when necessary.

11. Members and visitors shall remain seated until the presiding officer has declared the meeting adjourned.

Mrs. Roden of San Francisco County moved these rules be accepted. Seconded by Mrs. Annis of Los Angeles County. Carried.

Mrs. Doane of Los Angeles County moved the dues remain the same as last year. Mrs. Sargent of Alameda County seconded the motion. Motion carried.

The president, Mrs. Thomas J. Clark, called the vice-president, Mrs. William Sargent, to the chair. The president then gave her message, in which she spoke of her work and her pleasure in serving in the capacity of president of the Woman's Auxiliary. Mrs. Doane moved this report be accepted with a rising vote of thanks. Seconded by Mrs. A. J. Annis of Los Angeles. Motion carried.

The president resumed her chair and called upon Mrs. David Froehlich, corresponding secretary, to make her report.

Mrs. Frank Makinson, treasurer, reported.

The auditor's report was red by the recording secretary, Mrs. C. Kelly Canelo. This showed a balance on hand as of May 18, 1936, of $647.81. Mrs. Condit of Alameda County moved this report be accepted. Seconded by Mrs. Geiger of San Francisco County. Carried.

The following standing committee chairmen reported:

Mrs. Sargent, chairman of Membership and Organization, reported the addition of five new counties, thus giving California the honor of having the highest number of newly organized counties in the national organization.

Mrs. John Barrow, chairman of Program and Health Education, reported great improvement in programs throughout the State.

Mrs. Ray Carr Green, Public Relations chairman, reported assembly districts formed in Los Angeles, Orange and Fresno Counties.

Mrs. Arthur Annis, Public Health Activities chairman, reported outstanding activities were: a Public Health Institute in Alameda County, and San Diego gave over one day for public health talks given by physicians. These talks were for the public.

Mrs. Doane submitted the report of Mrs. Elmer Belt, Editor and Publicity chairman, who was unable to be present.

Mrs. Mark Glaser, *Hygeia* chairman, reported increased subscriptions, with Contra Costa in first place with a rating of 150 per cent.

Mrs. Andrew Thornton, Finance chairman, presented the financial report and budget.

Stationery	$ 75.00
Stenographer and clerical help	125.00
Postage	60.00
Telephone and telegraph	60.00
Convention	275.00
Editor and Publicity chairman	75.00
President's traveling expenses	225.00
Organization chairmen's traveling expenses	50.00
Miscellaneous	30.00
Total	$975.00

Mrs. Percy moved these reports be accepted as a whole, with appreciation, and placed on file. Mrs. Geiger seconded the motion. Motion carried.

Secretary read the recommendations from the State board made at the pre-convention meeting:

1. The president recommended a standing rule be made whereby funds of a sufficient amount be provided to cover the expenses of a round trip ticket to the national convention for the year corresponding to her year of office.

2. If the cash on hand at the end of the year exceeds $500 the surplus above this be placed in a savings fund which may not be drawn upon except for special purposes recommended by the vote of the State Board.

Mrs. Colby, convention chairman; Mrs. Mark Glaser, Mrs. A. J. Annis and Mrs. J. V. Barrow presented recommendations which were unanimously adopted. (Copy attached to the minutes.)

The president then made some announcements.

Appointed on Resolutions Committee are: Mrs. Tease, Mrs. Lee and Mrs. Colby.

The president announced that Mrs. William Sargent as chairman and Mrs. Harry Hund of Marin County had been elected by the board to serve on the Nominating Committee with three other members who were elected from the floor as follows: Mrs. Philip Stevens by Mrs. Doane, Mrs. Charles Howard by Mrs. Black and Mrs. Clarence Page by Mrs. Trimble.

There being no further business, the meeting adjourned.

Respectfully submitted,

Mrs. C. Kelly Canelo, *Recording Secretary.*

Minutes of the Second Session of the Seventh Annual Meeting of the Woman's Auxiliary to the California Medical Association

Wednesday, May 27, 1936.—The second session of the seventh annual meeting of the Woman's Auxiliary to the California Medical Association convened at 9:30 a. m. at the Coronado Yacht Club, Wednesday, May 27, 1936, with Mrs. Thomas J. Clark, president, presiding.

Mrs. David Froehlich, chairman of the Credentials Committee, reported forty-one delegates registered, twenty-nine alternates, twelve guests, sixteen board members, 116 Auxiliary members, making a total of 214.

The recording secretary called the roll of the State Board members and of the delegates by counties.

The minutes of the first session of the seventh annual meeting were read by the recording secretary and approved.

Mrs. Froelich read two telegrams: From Mrs. A. M. Henderson of Sacramento and Mrs. Louis H. Dyke of Oakland.

Mrs. E. E. Coulter, historian, being absent, Mrs. Doane read her report and presented the book for the history of the Auxiliary complete, from its inception to the present time.

Mrs. Henderson of Santa Barbara County moved the report of the historian be accepted. Mrs. Barrow seconded the motion. Carried.

Mrs. Clark announced Mrs. Doane had been elected third vice-president of the National.

Reports of the councilors at large were ready by: Mrs. Annis of Los Angeles County, Mrs. Ray Carr Green of Orange County, Mrs. Mark A. Glaser of Los Angeles County, Mrs. Frederick Scatena of Sacramento County.

Mrs. Geiger of San Francisco County moved these reports be accepted. Mrs. Cox of San Francisco County seconded. Motion carried.

The president then ordered these reports placed on file.

Reports of the district councilors were given as follows:

1st District—Mrs. Elliott Colby.

3rd District—Mrs. N. N. Brown.

5th District—Mrs. John Hunt Shephard.

6th District—Mrs. Geiger gave the report for Mrs. Becker.

7th District—Mrs. Fernandez gave the report for Mrs. Weill.

8th District—Mrs. Junius Harris.

9th District—Mrs. Harry Hund.

No objections being offered, the president declared these reports accepted and placed on file.

Report of county presidents were given as follows:

Alameda—Mrs. Page reported for Mrs. Sutterland.

Contra Costa—Mrs. Fernandez reported for Mrs. Carpenter.

Fresno—Mrs. Anderson reported for Mrs. Manson.
Kern—Mrs. N. N. Brown.
Lassen-Plumas—Mrs. Froelich read report from Mrs. Davis.
Los Angeles—Mrs. Barrow.
Marin—Mrs. Robert M. Furlong.
Orange—Mrs. Ray C. Green.
Riverside—Mrs. Hervey S. Faris.
Sacramento—Mrs. Frederick Scatena.
San Diego—Mrs. Emil C. Black.
San Francisco—Mrs. J. C. Geiger.
San Joaquin—Mrs. Brodius reported for Mrs. Langdon.
Santa Barbara—Mrs. Hunt reported for Mrs. Pierce.
Santa Clara—Mrs. Russell Lee.
Siskiyou—Mrs. Seely sent in a report.

Mrs. Annis of Los Angeles County moved these reports be accepted and placed on file. Seconded by Mrs. Frank Makinson of Alameda. Motion carried.

The report of the Committee on Resolutions, with Mrs. Chester Teass as chairman, was read and accepted. Motion of acceptance made by Mrs. Scatena, seconded by Mrs. Geiger. Carried.

The report of the Nominating Committee was read by Mrs. William Sargent, chairman, as follows:

President-elect, Mrs. Solomon N. Weil of Contra Costa County; First Vice-President, Mrs. C. A. Wright of Los Angeles County; Second Vice-President, Mrs. John Barrow of Los Angeles County; Recording Secretary, Mrs. Hobart Rodgers of Alameda County; Treasurer, Mrs. Frank Makinson of Alameda County.

Councilors at Large—Mrs. Mark Glaser of Los Angeles County, Mrs. Robert M. Furlong of Marin County, Mrs. Rodin of San Francisco County, Mrs. Annis of Los Angeles County.

Respectfully submitted,

Mrs. Sargent,
Mrs. Hund,
Mrs. Howard,
Mrs. Paige,
Mrs. Stevens.

Mrs. Lee of Santa Clara County moved these nominations be closed. Seconded by Mrs. Shephard of Santa Clara County. Carried.

By unanimous viva voce vote the names presented for the offices provided for in the Constitution were elected and so declared by the president.

The president then announced elections were in order for district councilors for the following districts: 1, 2, 4.

1. Mrs. Dexter Ball of Santa Ana nominated by Mrs. Lundenmueller of San Diego, seconded by Mrs. Black of San Diego.

2. Mrs. B. H. Sherman of Los Angeles nominated by Mrs. Barrow, seconded by Mrs. Pallette of Los Angeles.

4. Mrs. George Walker of Fresno nominated by Mrs. A. E. Anderson of Fresno, seconded by Mrs. Brodius of San Joaquin County. Mrs. Anderson made the motion that those nominated be accepted. Mrs. Black seconded the motion. Carried.

Mrs. Clark then presented the president for 1936-37, Mrs. Andrew Thornton of San Diego, who was enthusiastically acclaimed by the assembly. Mrs. Clark then introduced the other incoming officers.

The final report of the Committee on Credentials was read by Mrs. David Froelich showing forty-one delegates, twenty-nine alternates, twelve guests, sixteen board members, 116 Auxiliary members, making a total of 214.

Mrs. Doane of Los Angeles County moved a vote of thanks be given the recording secretary for her splendid and efficient work. Seconded by Mrs. Percy of Los Angeles and carried.

Mrs. Clark thanked the Auxiliary members for their help and asked their support for Mrs. Thornton. A round of applause was given Mrs. Clark for her fine work as president.

The secretary then read the minutes of the meeting, which were approved as read. There being no further business, the meeting adjourned at 12 o'clock noon.

Respectfully submitted,

Mrs. C. Kelly Canelo, *Recording Secretary.*

Nothing in human experience outranks learning. By it alone man rises above dumb creatures. If, therefore, we have received nothing else so good as the mind, what should be more worth cultivating? No quest of gold or worldly power has in the long run ever brought like gratification. No other adventure is to be compared with it. Through it civilization and all man's higher achievements have been won.

Another quaint custom is passing away: College graduates are becoming less prone to frame their diplomas and hang them on walls for callers to admire. So vanishes one more of our whimsies that used to divert cultivated European travelers, like Spencer and Dickens. Decorating offices and parlors in that way was linked with the notion that to be graduated was to have finished one's education.—U. C. Extension Division.

Education is a life-long process. Much of it goes on spontaneously. In that way it goes on when as infants we are finding our hands; and is still going on years later when, with those same hands, we endorse a speculator's note. Every experience leaves with us an educational by-product. In numberless ways we learn, yet remain the while unconscious that we are being schooled. It is only when we become aware of some lack in ourselves, some deficiency, that we are stirred to the point of making a conscious effort to learn.

Human Side of Practice.—It may be that the real meaning of the human side of practice will not come to you until as the family doctor you enter the home where with no intern, no attending man, you must shoulder the full responsibility for the treatment of a serious illness. You are making your evening visit on the man with pneumonia. He is an interesting case. You record with care the physical signs, the blood count, and the blood pressure. You are leaving the final directions for the night. The patient's breathing is rapid and labored, the delirium is marked. As he moans with pain of the cough, you note the look of anguish on the face of the young wife who stands near with the two-year-old hanging to her skirt. There are signs that another baby will come soon. Suddenly you sense it all. The loss of this husband, this father, this wage-earner, means not only a broken heart. It means wrecked hopes, a shattered home, the wife the future wage-earner. You say, you scarcely know why: "This may be a critical night; I will stay." You have unconsciously transmuted your emotion into an act of service. The look of gratitude from the dim eye of the wife is your ample reward. You have learned something of the human side of practice. The patient is a case, to be sure, but the case is a man.—John B. Herrick, M. D.

Figurative Language.—We doctors too often forget that patients do not always grasp our meaning because we employ language they do not understand.

I could not convince a man of sixty-five that the trace of albumin in his urine was not of serious significance. On his report from the bureau of analysis was the finger, rubber-stamped in violet ink, pointing to the word albumin. This outweighed all my reassurances. One day I said: "Why do you not worry about your wrinkles and your gray hair?" "Why, doctor," he said, "am I not entitled to gray hair at sixty-five?" "You are," I replied, "and so you are to have a trace of albumin in the urine. Your trouble is simply gray hair in the kidney." I saw him no more for two years, when he again came to see me. "You don't remember the circumstances, doctor, but I was upset by your statement. I went to another doctor, who promptly found Bright's disease. When he asked me what your diagnosis had been and I told him 'gray hair in the kidney,' he was indignant and furious. He said he had never heard such a fool diagnosis in all his life. He had always thought Doctor Herrick, etc." *Haec fabula docet:* Beware of using figurative language in speaking to a patient who is literally minded.—John B. Herrick, M. D.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

Proposed Initiative to Open County Hospitals; Interesting Newspaper Item on Insufficiency of the Petitions.—The Lodi, California, *News-Sentinel* of July 14 printed the following item:*

VOTE DELAYED ON HOSPITAL PAY POLICIES

A decision to postpone the vote upon the constitutional amendment which would allow pay patients to enter the county hospital was announced at the meeting of the directors of the San Joaquin County Farm Bureau in Stockton Saturday. Therefore, the measure will not be on the ballot at the November election.

Two reasons were cited by Harvey S. Van Vlear, secretary, for the decision. One was that the California ballot at the next election will contain about forty proposals and it is feared the pay patient proposition might not be given adequate study.

The other reason, Van Vlear said, is that while supplementary filing of names is permitted after the deadline on petitions, the Farm Bureau feels that it would have insufficient time to obtain enough names if large percentages were rejected by county clerks in checking the lists.

Circulation of the petitions will continue, and the petitions will be filed soon after the necessary 186,000 signatures are obtained, Van Vlear announced.

Filing of the petitions will make the proposal eligible for the next general or special state election. The secretary pointed out that it is more than likely that the issue will be voted on at some special state election before the next general poll.

Up to Friday night 100,000 voters had signed the petitions, but county clerk rejections were rather heavy, said Van Vlear. The entire state, he said, is looking to San Joaquin and Kern counties for leadership in the campaign. San Joaquin County will obtain 25,000 signatures to the petition before the drive is halted here, Van Vlear said.

I. N. Robinson, chairman, finance committee, reported the party given recently by the Farm Bureau in the Civic Memorial Auditorium netted $1,147.39.

Stockton "Independent" Discourses Editorially on the "Open the County Hospitals to Pay Patients" Initiative.—In connection with other items and comments in this issue, the following, from the Stockton *Independent* of July 15, should be of interest:

HOSPITAL PETITION WILL NOT FAIL

It is a matter of regret that the Farm Bureau faces conditions that make the filing of the hospital initiative petition near impossible and probably inexpedient at this time.

There are 25,000 voters, and to spare, in this county who would be ready signers if the petitions were laid on the table before them. But there are physical limitations on what even the civic spirited Farm Bureau workers can do. The quota of signers for this county is undeniably large. It was made necessary by the fact that the hospital issue is acute in only about one dozen counties. Hence, it is hard to have volunteer workers in communities that know nothing of the question at stake.

Then, too, there is good reasoning in the bureau's conclusion that this would be a poor year to put such a localized issue on the big ballot. Presidential issues engross public attention, and already scores of propositions encumber the ballot that will be laid before the people. There are proposals on which vast sums will be spent in the form of propaganda. Naturally these will be shoved to the front. A proposal like that of keeping the doors of a county hospital open to pay patients, with no big fund to publicize it, would be exposed to failure through public indifference or misunderstanding in counties that are not interested.

The decision of the bureau to go ahead and complete the petitions, as to the number of signers required, even

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

* See also editorial comment concerning this proposed amendment in this issue (page 113).

if several more months are required for the work, is wisely foresighted.

The completed petition will be a powerful argument before the legislature; and if the law makers should fall down before the spell of the state medical society, the petitions will be ready for use at the next election.

The *Independent* commends the men and women of the Farm Bureau and Secretary Van Vlear for their good work in the good cause. Let them "fight it out on this line if it takes all summer." *The "Independent" is enlisted for the duration of the war, and will stand behind them until victory comes.*

Stanford University School of Medicine Postgraduate Courses.—A series of postgraduate medical courses for practicing physicians will be given by Stanford University School of Medicine in coöperation with the San Francisco Department of Public Health and the San Francisco Hospital during September 14-18, 1936, inclusive. There will be a registration fee of twenty-five dollars. Each physician may take a morning and an afternoon course and all physicians should attend the evening general meetings. Registration closes September 10, 1936. Applications for registration in these courses should be mailed to the Dean, Stanford University School of Medicine, 2398 Sacramento Street, San Francisco, not later than September 10.

The courses follow:

MORNING COURSES

Course 1—Obstetrics and Gynecology

Monday, Tuesday, Wednesday, Thursday and Friday, 8:30-12:00.

This course will review the female pelvis and its relation to labor; maternal and fetal metabolism during pregnancy, toxemias of pregnancy; an analysis of menstruation with relation to associated endocrinology, cardiac disease and anemia; treatment of dysmenorrhea, ectopic gestation; birth control and contraception.

Course by Doctors L. A. Emge, C. F. Fluhmann, T. H. Kelly, A. V. Pettit, K. L. Schaupp, H. A. Stephenson, and Hans Von Geldern.

Course 2—Gastro-enterology

Monday, Tuesday, Wednesday, Thursday and Friday, 8:30-12:00.

This course will review methods of examination, general considerations of diseases of the gastro-intestinal tract; the medical and surgical aspects of diseases of the esophagus, peptic ulcer, biliary tract, colitis, appendicitis, intestinal obstruction, and gastro-intestinal malignancies. All discussions will be illustrated by case records, patients, lantern demonstrations, x-rays, etc. No operative clinics.

Course by Doctors A. L. Bloomfield, W. W. Boardman, Edmund Butler, L. R. Chandler, Garnett Cheney, P. K. Gilman, E. F. Holman, G. W. Nagel, R. R. Newell, R. A. Scarborough and H. A. Wyckoff.

Course 3—Pediatrics

Monday, Tuesday, Wednesday, Thursday and Friday, 8:30-12:00.

This course will review four general groups of pediatric problems: (1) The care of normal infants and children, including infant feeding; (2) the prevention of disease, including deficiency diseases and methods of immunization; (3) the commoner disorders and diseases of childhood, including the communicable diseases; (4) disturbances of mind and behavior, and methods of child guidance. Surgical problems also will be discussed. The course will consist of lectures, clinics, presentation of cases, and class discussions.

Course by Doctors W. C. Black, L. R. Chandler, L. B. Dickey, H. K. Faber, M. H. Layman, D. C. Marshall, M. I. Preston, A. P. Purdy and R. P. Seitz.

Course 4—Cardiology (Limited to fifteen physicians)

Monday, Tuesday, Wednesday, Thursday and Friday, 8:30-12:00.

The examination and study of cardiac patients by small groups will be supplemented by discussions and the demonstration of methods, use and interpretation of electrocardiography, and fluoroscopy.

Course by Doctors William Dock, J. K. Lewis, W. W. Newman and J. M. Read.

* * *

AFTERNOON COURSES

Course 5—Hypertension and Nephritis

Monday, Tuesday, Wednesday, Thursday and Friday, 1:30-5:00.

This course primarily will cover office management of patients with hypertension and nephritis, using certain simple methods of examinations of blood and urine. These facts will be used as a basis for discussion of treatment. Approximately quantitative dietetic methods will be used.

Course by Doctors Thomas Addis and D. A. Rytand.

Course 6—Neurology and Psychiatry

Monday, Tuesday, Wednesday, Thursday and Friday, 1:30-5:00.

This course will consider the diagnosis and treatment of the common disorders of the central nervous system with special emphasis on the treatment of the psychoneuroses in general practice and a consideration of special problems in neurosurgery and neuropathology.

Course by Doctors Joseph Catton, G. S. Johnson, H. W. Newman, F. L. Reichert and W. F. Schaller.

Course 7—Fractures and Traumatic Surgery

(At San Francisco Hospital)

Monday, Tuesday, Wednesday, Thursday and Friday, 1:30-5:00.

This will be an informal course on the examination and treatment of fractures, use of local anesthesia, demonstrations of application of plaster, adhesive and skeletal traction, skull fractures, surgical approaches (cadaver), joint derangements, fracture follow-up clinic, infections of the hand.

Course by Doctors N. J. Howard, D. E. King, Carleton Mathewson, E. J. Morrissey and E. B. Towne.

Course 8—Proctology (Limited to fifteen physicians)

Monday, Tuesday, Wednesday, Thursday and Friday: 1:30-5:00.

This course will review common lesions of the large bowel, rectum, and anus, including common methods for office practice, operative indications and technic, pathology, differential diagnosis, etc.

Course by Doctor Scarborough.

Course 9—Otorhinolaryngology (For specialists only; general practitioners are not eligible for this course)

Monday, Tuesday, Wednesday, Thursday and Friday, Mornings, 9:00-12:00; afternoons, 2:00-5:00.

This course will cover anatomy, physiology, pathology; practical operative work on cadavers; treatment of diseases of the ear, nose and throat.

Course by Doctors, R. E. Ashley, J. A. Bacher, C. B. Cowan, S. v. Christierson, F. D. Fellows, H. A. Fletcher, H. B. Graham, H. Y. McNaught, R. C. McNaught, A. G. Rawlins and E. C. Sewall.

An additional fee of $7.50 will be charged to cover the cost of anatomical materials used in this course.

* * *

General meetings will also be held each day in Lane Hall, 8:00-10:00 p. m.

Meeting 1—X-Ray Therapy

Dr. Robert Newell and staff

Monday evening, 8:00-10:00

Meeting 2—Backache

Doctors A. L. Bloomfield, D. E. King and L. A. Emge

Tuesday evening, 8:00-10:00

Meeting 3—Blood Diseases

Doctors H. P. Hill, H. A. Wyckoff and Garnett Cheney

Wednesday evening, 8:00-10:00

Meeting 4—Syphilis, Diagnostic Methods and Therapeutic Agents

Dr. C. W. Barnett

Thursday evening, 8:00-10:00

The Prevention of Cancer.*—Among the silent and sinister economic leeches which sap the blood of civilization, few do a more thorough and tenacious job than does cancer. All the material which the world needs for the greater proportion of cancer is education and the opportunity to obtain, at a low cost, the professional or medical help for which such education calls. Cancer is a disease that thrives on ignorance and must be fought with knowledge.

Fortunately cancer can be prevented. Some of the preventive measures are:

1. The observation of scrupulous cleanliness of the skin, the mouth cavity and the genital canal. This means

---

* From Clinical Medicine and Surgery, December, 1935.

the avoidance of infections or, if they occur, the obtaining of medical treatment to cure them.

2. Moderation in everything concerning the daily life and habits, especially in the use of tobacco; moderate and slow eating; avoidance of food and drinks that are either too hot or too cold or too irritating, such as alcohol in high concentration.

3. The avoidance of chronic constipation end of the consumption of irritating foods, not by using cathartics but by training the bowel to function regularly and by acquiring the habit to devote a daily, regular time to this function.

4. Keeping the body in a perfect state of health by regular hours of rest, sleep and exercise. One should sleep regularly eight hours and spend at least several hours daily in the open air with moderate exercise, such as walking, swimming, riding, golfing, tennis, bowling and so forth.

5. The periodic examination; that is, a yearly examination of men and women and the examination, in women, of the breasts and the genital system, especially after pregnancy and labor, and yearly after the thirty-fifth year of life. The preferable day would be one's birthday as this day is not easily forgotten and such an examination is a fine birthday present.

6. The immediate reporting to the family physician of any lump on the body, of any sore that does not heal within a week, of any discharge or bleeding from any of the body openings, as the nose, the mouth, the genital or urinary canals and the rectum.

The conscientious family physician will refer the patient to a specialist or clinic for an immediate correct diagnosis, after the examination, if he cannot make it. Many conditions (probably 95 per cent) will not be cancerous, and those that are will be detected and offered the best guarantee of a permanent cure if immediately and adequately treated. Those that are not malignant can be treated without great discomfort and at slight expense and the chronic tissue changes are thereby removed.

Los Angeles City Receiving Hospital.—The Los Angeles *Herald-Express* printed the following item, the last sentence being of especial interest:

> RECEIVING HOSPITAL MADE INDIVIDUAL UNIT BY COUNCIL
>
> An ordinance divorcing the receiving hospital from its present affiliation and permitting it to function as an individual unit whereby the chief surgeon will become the general manager of the institution subject to city council appointment, passed first reading in council yesterday, records today disclosed.
>
> While the general manager will be appointed by the city council, other offices will be filled by the chief of police from available civil service rolls, it was announced. Operation of the institution will not be changed. All residents of the city, including city firemen and policemen, will be treated free of charge. Slight opposition developed in the council chambers yesterday over the absence of a provision in the ordinance stating that treatment of firemen and policemen should be limited to injuries received only in line of duty.

California Industrial Accident Commission.—There were in all 262,955 industrial injuries reported for the calendar year 1935, an increase of 32,054 injuries or 13.8 per cent.

Of these, 551 caused death, an increase of 124 deaths or 29.0 per cent in comparison with the calendar year 1934; 748 caused a permanent impairment of at least 1 per cent, an increase of sixty permanent disabilities or 8.7 per cent; 71,488 caused a temporary disability lasting longer than the day of injury, an increase of 5,595 temporary disabilities, or 8.4 per cent; 190,168 were no-disability cases but which required medical service other than ordinary first aid treatment, an increase of 26,275 no disabilities or 16.0 per cent.

The principal industries for which increases were reported were agriculture 9.3 per cent increase, mining and milling 8.4 per cent, foods and beverages manufacturing 9.6 per cent, lumber and wood manufacturing 7.0 per cent, building construction 7.6 per cent, stevedoring and freight handling 8.9 per cent, railroad operation 9.0 per cent, and motion picture production 63.6 per cent.

National Medical Council on Birth Control.—The National Medical Council on Birth Control was organized in June, 1936, for the following purposes:

1. To control and supervise all medical policies of the American Birth Control League.

2. To initiate, encourage, and execute appropriate scientific research in the medical aspects of birth control.

For information, apply to 515 Madison Avenue, New York, N. Y.

Los Angeles Cancer Society.—The Los Angeles Cancer Society held its first regular meeting on June 17, 1936, in the County Medical Building, and was attended by some thirty men, to be known as charter members, who are appointees from the various accredited hospitals in and about Los Angeles, including a group from the Pasadena Hospital, United States Veterans' Hospital at Sawtelle, Santa Barbara Cottage Hospital, Santa Barbara; also groups from the Los Angeles General Hospital, California Lutheran, Cedars of Lebanon, Good Samaritan, Hollywood, Methodist, Queen of the Angels, St. Vincent's, White Memorial, and a representative from the American Society for the Control of Cancer.

The purpose of this society as covered by the by-laws is to "bring together physicians interested in the study of cancer and allied neoplastic diseases and for correlating activities of the several committees or boards for study of cancer."

The membership is composed principally of pathologists, surgeons, radiologists, internists, and other men vitally interested in the cancer problem. Members of the Los Angeles County Medical Society wishing to join the Los Angeles Cancer Society may do so by making application to the secretary for approval by the members of this society.

Officers elected for the year include: President, Dr. Newton G. Evans; vice-president, Dr. William E. Costolow; secretary-treasurer, Dr. C. Hiram Weaver; Executive Committee, Doctors George S. Sharp, James F. Percy and Donald G. Tollefson.

Regular meetings will be held four times each year with the Executive Committee empowered to call extra ones as they deem necessary.

National Nursing Convention: Los Angeles Session. California nurses, California skies and California sunshine all gave a radiant welcome to the thousands of nurses who attended the great 1936 National Biennial Nursing Convention in Los Angeles, June 21 to 26.

Teas, dinners, luncheons and breakfasts—both formal and informal—were held by divisions and sections of the American Nurses' Association, by reunited friends, alumnae associations and public health nurses. Local groups—the hospitals, visiting nurse associations and Red Cross Chapter—opened their doors to the visitors, and even the Los Angeles sheriff invited the nurses to a cup of tea in jail—with a visit to the prison hospital thrown in!

The convention program was filled to the hilt with interesting meetings of all kinds. Meetings started early—in fact, officers of the associations started the day around 5:30 a. m., in order to assemble facts, materials and ideas necessary to assure the smooth running of sessions. Getting an early breakfast was a problem! When the Ambassador Hotel was asked to serve that important meal at 5:30 one morning, the answer was that it was not a working man's hotel! Consequently, breakfast could not be had until 6:30!

Approximately 6,000 nurses registered, and several thousand more, though omitting the detail of registering, attended the meetings.

All nurses who attended the convention except those from the North and Hawaii, were Easterners, according to the Californians. Said a California nurse to a New Yorker: "I'm looking for a nurse from the East. I wonder where I could find her." "What part of the East is she from?" asked the New Yorker. "Nebraska," was the answer!

American Congress of Physical Therapy.—Announcement is made of the fifteenth annual clinical and scientific session of the American Congress of Physical Therapy, September 7, 8, 9, 10 and 11, at the Waldorf-Astoria, New York City. The program includes many special features: sectional meetings in the specialties, symposia on short wave diathermy, hydrotherapy, exercise and electroresection. Fever therapy and the treatment of vascular diseases occupy an important place and will be discussed by prominent workers in the field. The educational aspects of physical therapy and the relationship of physical therapy technicians to physicians and hospital departments will be thoroughly dealt with. Other features include technical and scientific exhibits and a full day of hospital clinics where technique will be adequately demonstrated.

First International Conference on Fever Therapy.—The first International Conference on Fever Therapy, originally scheduled for the end of September, 1936, has been postponed because of numerous requests, to permit more time for the preparation of material. The new dates set for this conference are March 30 to April 2, 1937. The sessions will be held at the College of Physicians and Surgeons, Columbia University, New York City.

The advances in the treatment of gonorrhea, syphilis, and other diseases by pyretotherapy are of great social significance. Invitations on behalf of the conference will be issued by the State Department of the United States to Ministries of Public Health of other countries. The medical departments of the Army, the Navy, and the Public Health Service of the United States of America will be represented, as will also the New York City Departments of Health and of Hospitals.

A tour has been arranged to take place immediately following the conference, to enable physicians to observe the techniques employed in fever therapy in some of the hospitals in the eastern section of the United States. Among the institutions to be visited are the Strong Memorial Hospital of the University of Rochester, New York; the Henry Ford Hospital, Detroit; the Mayo Clinic, Rochester, Minnesota; the Kettering Institute for Medical Research at the Miami Valley Hospital, Dayton; Northwestern University Medical School, Chicago.

Further information regarding the conference may be obtained from the general secretary, Dr. William Bierman, 471 Park Avenue, New York City, U. S. A.

XV Concilium Ophthalmologicum.—According to the decision of the Fourteenth International Congress held in Madrid in April, 1933, the next Congress will be held in Cairo, Egypt, under the high patronage of H. M., the King of Egypt.

In conformity with the decision of the International Council of Ophthalmology, London, April, 1935, the meetings will be held from December 8 to 14, 1937.

The two official subjects of the Congress will be:

1. Arterial Hypertension of the Retina.
2. Endocrinology and the Eye.

Two exhibitions will be arranged:

1. *A Scientific Exhibition*, comprising anatomical and pathological specimens or slides, photogrphs, radiographs, etc. Members wishing to partake will please communicate with the secretary general, stating the object to be exhibited, its size, etc.
2. *A Commercial Exhibition*, comprising instruments, apparatus, drugs, printed matter, etc.

Inscription for membership to the Congress is open for every medical man, and those who desire should write for the enrollment form and send it to the secretary general, as early as possible, together with the sum of 50 Swiss francs, to cover the fees for subscription. The fees for ladies and other associate members of the congressists' families are 25 Swiss francs per person—those can attend receptions, excursions, etc., but are not entitled to attend the scientific meetings, nor will they receive a report of the proceedings of the meetings.

All correspondence should be forwarded to the secretary general, XV Concilium Ophthalmologicum, P. O. B. No. 2001, Cairo, Egypt.

Hay Fever and Other Allergic Diseases.—A chemical study of substances in agricultural products and by-products that contribute to the allergic disturbances—hay fever, asthma, hives, and related afflictions—is being established in the Bureau of Chemistry and Soils of the United States Department of Agriculture, Dr. W. W. Skinner, assistant chief of the bureau, announced today.

One-tenth of the population of the country suffer seasonal distress or continual discomfort and restricted activity as the result of allergic diseases known by such familiar names as hay fever, pollen fever, rose fever, rose colds, asthma, hives, and so on. These afflictions affect people of all ages. Some individuals suffer from abnormal sensitiveness to certain normal constituents of the pollens produced by many varieties of trees, grasses, and weeds. Similar substances present in common foods, textile fibers, furs, and other farm products are also capable of causing distressing disturbances when absorbed through the skin or the membranes of the respiratory or digestive systems of supersensitive persons. Chemists and specialists in other lines of scientific investigation will attempt to isolate these offending components and to determine their composition.

Dr. Henry Stevens, biochemist of the Protein and Nutrition Division of the Bureau of Chemistry and Soils, is organizing the staff which will undertake the allergen investigations. Dr. Harry S. Bernton, Professor of Hygiene at the Georgetown University Medical School, has been appointed consulting specialist in allergy and will participate in the department studies of the allergens.

Funds for this investigation, provided by the Bankhead-Jones Act, signed by President Roosevelt a year ago, will enable the Federal Department of Agriculture and state agencies to proceed with long-deferred researches of fundamental significance to agricultural science.

Leon Asher, M. D.*—An interested and interesting visitor to the United States this summer is Dr. Leon Asher, 71-year-old professor of Physiology, University of Berne, Berne, Switzerland. Invited by the Mayo Clinic to present a series of lectures on physiology, Doctor Asher's dynamic personality and original views have extended his fame over the country so rapidly that he was besieged with more invitations to address university and medical groups than he could accept. In the course of his tour of the United States with Mrs. Asher, he addressed large audiences in the middle west, the northwest and along the Pacific Coast, returning to Switzerland late in Junue. Professor Asher was a guest speaker at the California Medical Association Coronado annual session.

Interviewed by the editor of *Food Facts* after his address to the Minnesota State Medical Association at Rochester, Minnesita, on May 5, Doctor Asher expressed himself as bewildered by the great variety of dietary fads that he has encountered during his visit. He says Americans are altogether too worried about the state of their heatlh and the kind of food they eat.

"We have food faddists in Switzerland, but in no such number as are to be found in the United States," commented the venerable professor, who at 71 is as hale and hearty as a well preserved man of 50.

"Man has not lost his instinct to select the kind of food his body needs," continued the doctor. "Taste is an important factor in food selection, but food faddists often influence people to stop eating what they like and what is good for them. An outstanding example of this is bread. It is one of our basic foods that has suffered from unfair attacks by food faddists."

Doctor Asher says that about the same types of bread eaten in the United States are served in Switzerland. The favorite breadstuff of the Swiss is the hard roll made of white flour, although such breads as whole wheat, rye, etc., are used for variety. Almost all of the flour used in Switzerland is imported.

"You can't beat good white bread and milk as the foundation of any diet," says Doctor Asher, "and the two alone make a nourishing lunch sufficient for any man."—*Food Facts*.

---

* Professor Leon Asher was a guest speaker at the Coronado annual session of the California Medical Association, May 27, 1936.

Tuberculin Testing of California Dairy Herds.—On page 91 of the July, 1936, issue of California and Western Medicine was printed the resolution on Tuberculin Testing of California Dairy Herds, adopted at the recent Coronado annual session by the House of Delegates. On this same subject, the Los Angeles *Herald-Express* of July 22 printed the following item:

CATTLE TESTS COVER WIDE CALIFORNIA AREA

By United Press

SACRAMENTO, July 22.—With the start of work recently in Colusa County, the Federal bovine tuberculosis eradication program in California has been extended to twenty-three counties, it was announced here.

In the past month most of the Federal testing, authorized under the Jones-Connally act, has been done in the counties of Humboldt, Sonoma, Marin, San Joaquin, Fresno, Kings and Tulare.

"Under the Federal-state coöperative eradication program, retesting of previously infected herds has been conducted recently in the counties of Del Norte, Butte, Orange and San Bernardino," a report of the State Department of Agriculture said.

Reduce Infection

"By reason of the eradication work, extent of infection in those counties has been reduced to a very low point. Retesting has been started more recently in Santa Barbara, Los Angeles and San Diego counties. In the eradication of bovine tuberculosis it is necessary to retest herds periodically in order to assure the elimination of possible sources of infection."

The report also pointed out that testing under the pure milk provisions of the state law has been completed in San Luis Obispo, Monterey and San Benito counties.

Milk Tested

"This work is required in connection with the law covering distribution of dairy products in the raw state for human consumption," the report explained. "If the cattle are not free from tuberculosis as indicated by tests, the dairy products must be pasteurized. This pure milk testing is conducted regularly by the department in counties which have not been designated tuberculosis control areas."

It was announced recently by Los Angeles health authorities that northern California cattle which have not undergone non-tuberculin tests would be banned from Los Angeles. The order was held necessary because of activities of minority groups in refusing to have their herds tested.

LETTERS

Concerning status of proposed "Open County Hospital Initiative"; report from Public Health League.*

Los Angeles, July 22, 1936.

To the Editor:—We have just completed a check-up on the county hospital proposition with the results as noted in the enclosed. I thought perhaps you might want to use this in California and Western Medicine.

With kindest personal regards, I am

Sincerely yours,

Ben H. Read,
Executive Secretary.

563 Chamber of Commerce Building.

* * *

The Public Health League reports that a survey of all of the counties of the state indicates that scattered petitions for the County Hospital Initiative were filed in eleven counties with a total of approximately 12,500 valid signatures. Sponsors of the proposal had notified their local committees not to file the petitions at this time and had wired several county clerks not to accept petitions. But a few were filed in eleven counties despite these instructions.

In announcing that the county hospital proposal would not be placed on the November ballot, Harvey S. Van Vlear, secretary of the San Joaquin County Farm Bureau, gave two reasons: one that the ballot will contain about forty proposals and it is feared the hospital plan would not receive adequate study. The other reason was that heavy rejections of signatures by county clerks might invalidate the petitions. It was stated that 100,000 voters had signed the petitions up to July 10.

The sponsors of the proposal have announced that they will continue to circulate the petitions until the required 186,000 valid signatures are secured—some time this fall. This will qualify it for the 1938 election or for any special election that may be called during the coming year. Commenting upon this strategy, the Stockton *Record* editorially hints that the issue may be used as a weapon when the legislature meets in January. The editorial says:

"By holding up the proposed initiative until a later election, sponsors of the movement will escape the necessity of trying to impress an obviously overburdened public. They will place themselves in a position to more carefully lay the groundwork for a campaign in a year when fewer diverting interests exist. What they have done to date will in no way lose its value. With the initiative ready to qualify at a moment's notice the issue will remain alive and may even serve a valuable purpose when the legislature meets."

Thus it is seen that this subject is still with us and will continue to be of paramount political importance until it finally reaches a vote of the people either in 1937 or 1938.

Concerning proposed initiative to open county hospitals to both indigent and pay patients.

July 7, 1936.

To the Editor:—The attached copy of a letter to Dr. Louis A. Packard, Bakersfield, is self-explanatory and is sent for your information.

With kindest regards, I am

Sincerely,

J. C. Geiger, M. D.
Director of Public Health,
City and County of San Francisco.

* * *

Louis A. Packard, M. D.
Bakersfield
California

June 30, 1936.

J. C. Geiger, M. D.,
50 Ventura Avenue,
San Francisco, California.

Dear Doctor Geiger:

I am taking the liberty to remind you by letter of the promise you made at Coronado following the meeting of the House of Delegates. I have been reminded on numerous occasions since that evening by other delegates who were present and heard the conversation and asked if you had offered any solution. Only this morning I received another communication from the northern part of the state to that effect.

Since you were so positive in your statement before the House of Delegates and since your comments were at least partly responsible for the application of the drastic tabling move we feel that you should carry out your promise to offer a solution. I am certain that all of those present felt that it would be no great effort on your part.

Awaiting your reply with pleasure, I am,

Sincerely yours,

Louis A. Packard, M. D.

* * *

Office of
Director of Public Health
City and County of
San Francisco

July 7, 1936.

Louis A. Packard, M. D.,
Haberfelde Building,
Bakersfield, California.

My dear Doctor Packard:

Thank you very much for your note of June 30, relative to the initiative petition now being circulated opening county hospitals for pay patients. As I had a previous communication from Dr. John W. Green, secretary of the Solano County Medical Society, on the same subject, which was submitted to the various members of my staff for certain suggestions, the same reply sent to him is being sent to you.

---

* See also editorial comment in this issue, on page 113.

During the conversation at Coronado I told you I would be very glad to submit my ideas with, of course, the realization that these are not a solution but just a personal opinion of the problem.

May I state most emphatically, as I did at Coronado, that the opening of county hospitals for other than indigents would be a sad mistake and should not be done. Furthermore, that the decision of the medical profession as represented at Coronado is correct in that it would oppose to the limit of its ability this initiative petition; that I am of the opinion that it should be done through education, publicity, paid advertising and through lay organizations, especially the taxpaying groups. Finally, the set-up of the San Francisco Department of Public Health is to me ideal, and this is what I had in mind in my conversation with you. I am sure, however, this set-up is familiar to you, but it is briefly as follows:

1. All county institutions dealing with the indigent ill, particularly the county hospital, are under the Director of Public Health, who presumably was appointed for his training in and knowledge of public health and who is a full-time employee.

2. At present the medical staffs, which include the attending and consulting staffs, are appointed by the deans of the two universities with the approval of the Director of Public Health, and in turn our institutions are used for the teaching of medicine in all its branches. Where universities are not available such staffs should be appointed by the Director of Public Health or the county health officer, for their ability in their particular field. Such appointments must come from the ranks of scientific medicine as we know and interpret it. If civil service status is established for the attending and consultant staffs, I would have no objection, provided the examining board had definite and high requirements and standards for the position before them, and were themselves extremely well qualified and came from the ranks of scientific medicine. The question of compensation or salary for such staffs is a controversial one, but my opinion has been decisive that they should serve without salary since there is always to be found devoted physicians to serve well the indigent ill. The resident staff, however, should be full-time adequately trained and paid and be responsible for out-patient activities, if any. All paid staffs of our institutions are likewise selected on the recommendations of the two deans of the two universities with the approval of the Director of Public Health.

3. No case is accepted for county institutions caring for the indigent unless it has gone through social service and no case is accepted without such investigation except on actual emergency and then on approval of the Director of Public Health.

4. The standards of social service investigations have been agreed to by the social service agencies of the city and county of San Francisco and are substantially as follows:

A social service division working under the Director of Public Health controls admissions. On application of a patient for admission a complete investigation is made to determine his eligibility for care. The social investigation includes a statement that the patient is in need of specific medical care, and cannot provide that care without depriving his legal dependents of the necessities of life. A bank authorization is also signed by the applicant and a report secured of any deposits he may have. A report is also received from the Assessor's office regarding any property he may have. Medical necessity for hospital care is determined by the admitting physician of the hospital.

Nonresident patients are admitted in emergency and given emergency care only. Accident cases that are admitted as emergency are immediately investigated and transferred to other hospitals as soon as condition permits such transfer after they are found able to pay. Such cases are billed at the per capita cost, rate set by resolution of the Board of Supervisors each year. All accident cases are billed on the expectation of possible payment. These bills are subject to cancellation by the controller. Where a patient or his responsible relatives under the state law are able to pay some part of their hospital cost, yet unable to meet the expense of a clinic rate hospital in the community, such adjustment is made at the time of admission by the Social Service Division. Where it is found that a patient has died in the hospital leaving an estate a "Creditor's Claim" is filed on behalf of the city and county.

In conclusion, the public fully realizes that no county hospital could render any scientific medical service to any patient as such without the aid and advice of the well trained physician, for the physician is the pivot around which revolves all service to patients. This statement must not be regarded as a threat to strike against this service for the ill, for the tenets of our profession forbid this, but how far the physician will go in taking the popularly designed so-called "walk" is not known to the writer. To open county hospitals for pay, part-pay patients, or to those patients subject to political favoritism, would be such an impossible situation and so detrimental to the interests of the indigent ill for whom county hospitals were originally erected and maintained that the medical profession would be called upon to take drastic and decisive action. Scientific medicine must not only face the situation of opposition to opening of county hospitals to all types of patients, but must take constructive steps to prepare proper facilities for medical care of the under-privileged and deserving group in which the hospital and the physician will serve them with credit and benefit to all concerned.

Sincerely,

J. C. Geiger, M. D.,
Director.

Concerning corporate practice of medicine: Recent Appellate Court decision.

June 30, 1936.

Re: Corporate Practice of Medicine: *Benjamin Franklin Life Assurance Company* vs. *Mitchell, Insurance Commissioner,* 85 C. A. D. 1058.

To the Editor:—The above entitled case was decided by the District Court of Appeal for the Second Appellate District on June 18, 1936. The general principle involved is the same as that involved in the case of Pacific Employers Insurance Company vs. Carpenter, 83 C. A. D. 916, with which you are familiar. However, the particular type of insurance policy which the Benjamin Franklin Life Assurance Company proposed to issue was somewhat different in its provisions from the policy concerned in the Pacific Employers Insurance Company case.

Although the result reached by the District Court of Appeal in the Benjamin Franklin case is the same as the result reached in the Pacific Employers case, it is worthy of note that the differences in the two types of policy were sufficient to cause one of the three judges in Benjamin Franklin Life Assurance Company vs. Mitchell to reach the conclusion that the issuance by that company of its proposed policy would not involve the corporate practice of medicine.

Stated as briefly as possible, the facts involved in the Benjamin Franklin case are as follows: The insurance company submitted to E. Forrest Mitchell, then insurance commissioner of the State of California, for his approval a form of insurance policy which provided for "indemnity against loss by reason of medical and hospital expenses occasioned by disease or injury suffered by the insured." The application form and the policy form provided in effect that each year all of the policyholders should elect a committee known as the "Policyholders' Committee of the Company," which committee should select physicians, hospitals, pharmacies, x-ray laboratories, etc. The physicians selected by the committee would be the only physicians from whom policyholders would be authorized to secure medical services under the policy. If a policyholder selected a physician on his own account, other than a physician approved by the policyholders' committee "all right to reimbursement for the expenses of any services for any condition arising out of or in connection with such treatment or care shall be forfeited hereunder."

The application for a policy contained a provision by which the policyholder appointed the policyholders' committee of the company his attorneys in fact and proxies for a period of seven years to represent the policyholder and to vote for him at all regular and special meetings of policyholders, including those meetings at which the committee itself should be elected. It seems rather obvious that the intent of the Benjamin Franklin Life Assurance Company was to control the personnel of the so-called "policyholders' committee."

Two of the three justices of the District Court of Appeal held that the foregoing insurance policy was fundamentally the same as the policy involved in Pacific Employers Insurance Company vs. Carpenter, that is to say, that it contemplated the corporate practice of medicine by the insurance company and that therefore the insurance commissioner did not err in refusing to approve the policy form.

The Benjamin Franklin Life Assurance Company argued that its policy was entirely different from the policy concerned in the Pacific Employers case because of the fact that policyholders, through a committee, selected their own physicians and because the company "does not undertake or agree to furnish any medical or other services to its members, nor does it undertake or agree to employ anyone to furnish such services, nor does it undertake or agree to pay to any person compensation who may furnish medical or other services." To this argument two out of the three justices replied:

> "This is literally true, but that which the company as such cannot do lawfully, it *requires* its members, by means of a contract with such members as individuals, to accomplish for it through the medium of a so-called 'Policyholders' Committee,' the creation of which is evidently provided for in the by-laws of the company. It should be noted, however, that the so-called Policyholders' Committee is not a committee of the policyholders but a committee *of the company*. The selection and designation of doctors by said Policyholders' Committee is, therefore, after all, but a selection and designation by the company. The creation of the committee is not a voluntary contribution of the members for mutual benefit, but is a condition contained in the policy at the time of the sale thereof. The company thereby undertakes to do indirectly what it cannot lawfully do directly."

The insurance company also argued that it proposed to do nothing more than has been done for the last eighty years or so by fraternal orders, lodges, religious organizations, benevolent associations, hospitals, hospital associations, labor unions and other employee associations which have been engaged in collecting periodic dues from their members for the purpose of furnishing them medical services to be rendered by doctors employed by such organizations on a salary basis and who are selected not by the patient but by the organization. The majority of the court stated that the Benjamin Franklin Life Assurance Company "is primarily engaged in the sale of medical service—by whatever name it may be called—sold through the medium of insurance. None of the features that are prominently characteristic of the above mentioned benevolent societies are included in the insurance company's so-called 'mutual association.'" Evidently the justices consider that with respect to the corporate practice of medicine there is a distinction between corporations operating for profit and non-profit organizations.

I believe that this case is of great importance. Considering the two cases (Pacific Employers Insurance Company vs. Carpenter and Benjamin Franklin Life Assurance Company vs. Mitchell) together, it seems rather clear that the Appellate Courts of this state have closed both the front door and the back door to the practice of medicine by corporations organized for profit.

We will watch the proceedings to see whether a hearing is applied for and granted by the Supreme Court.

Very truly yours,
Hartley F. Peart.

Concerning present-day plumbing equipment and need of engineering survey.

AMERICAN MEDICAL ASSOCIATION
Bureau of Health and Public Instruction
535 North Dearborn Street, Chicago

July 8, 1936.

Dear Doctor Kress:

Attached are some resolutions passed by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, which were adopted at the meeting of that committee in St. Louis, February, 1936.

In view of the potential importance of this problem, the publication of the resolutions or editorial comment thereon, or both, would be appreciated.

Very truly yours,
W. W. Bauer, M. D.

* * *

Resolution Adopted by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, June, 1936

Whereas, At the annual meeting of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association held at St. Louis, Mo., February 25, 1936, a presentation was made by Major Joel I. Connolly, of the Chicago Board of Health, relating to possible health hazards in apparently modern plumbing installations in public buildings, and

Whereas, It was manifest in the said presentation that plumbing fixtures which have been generally regarded as safe and sanitary in design may in fact constitute a real and serious health hazard by reason of the danger of back siphonage and contamination of water supply mains, and

Whereas, The probability exists that such apparently modern, safe and sanitary plumbing installations may exist in numerous school buildings in the United States, and

Whereas, The existence of such apparently safe, modern and sanitary plumbing installations and reliance upon them brings about a sense of false security, therefore, be it

Resolved, By the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association that this committee apprehends the possibility of danger to the health of school children from apparently safe, modern and sanitary plumbing installations in school buildings, and be it further

Resolved, That the said Joint Committee earnestly recommends to all school boards and school executives that surveys be instituted by competent engineers to ascertain whether or not the danger of back siphonage and consequent pollution of water supply mains exist in plumbing installations within their jurisdictions, and that such surveys be followed by prompt corrective measures, and be it further

Resolved, That these resolutions be offered for publication to all journals dealing with public health, health education and general education.

Concerning article on Harrison Narcotic Law. (See editorial comment on page 115, and U. S. District Court decision on page 164.

Los Angeles, July 16, 1936.

To the Editor:—I am mailing to you today a copy of the decision handed down by Federal Judge Yankwich in the case against me by the United States for violation of the Harrison Narcotic Act.

This decision should be of interest to every physician in the United States, as it clarifies the question as to who are to determine whether patients are pathologic: narcotic enforcement or physicians?

The indictments were filed against me because I dared to . . .

This fight has cost me a loss of time, money, practice and possibly reputation, and I feel that my defense should have been financed by the Los Angeles County Medical Society, as it was really a test case.

With kind regards, I am

Sincerely yours,
719 South Catalina Street. E. H. Anthony.

Concerning five-year nursing course.

June 23, 1936.

Dear Doctor Kress:

Enclosed find copy of an opinion dated June 19, No. 10632, from the office of the attorney general, in reference to the inquiry regarding the five-year nursing course.

Very truly yours,

W. M. Dickie, M. D.,

Director, California Department of Public Health.

* * *

State of California
Legal Department

San Francisco, June 19, 1936.

Hon. Walter M. Dickie,
Director, Department of Public Health,
313 State Building,
San Francisco, California.

Dear Sir:

I have your communication in which you state as follows:

> "Certain universities of this state are giving a five-year nursing course. They establish a definite curriculum for such courses, which curriculum commences upon matriculation in the university. At the conclusion of the courses diplomas and degrees are awarded to those satisfactorily completing the same.
>
> "Both universities require the matriculate to spend the first portion of each course on the university campus proper on the study of the basic sciences and the theory of nursing, and the last two years at the hospitals conducted by the respective institutions located elsewhere than at the campus. In such hospitals, practical teaching is provided as the concluding phase of the course curriculum.
>
> "A student at one of the universities is required to spend a portion of the third and fourth year of the university course on the university campus, and a portion of the course at the hospital, while the other university requires students to spend the first three years on the campus and the last two years at the hospital."

You ask if students registered before September 15, 1935, in the nursing courses given by such universities come within that portion of Section 4 of the Nurses' Registration Act (as amended in 1935) which permits applicants for certificates as registered nurses to qualify for examinations where they have had not less than twenty-eight months' instructions as required in said Act or whether such students must now complete a course of instruction of the character specified in said Act covering a period of not less than thirty-six months, as required of all applicants since the effective date of the 1935 amendment.

Your department has heretofore been advised that, if a nursing school gave a course of instruction approved by the board and as required by the law and the regulations promulgated by the Board of Public Health, it would constitute "an accredited school of nursing," as such expression is used in said Act. (Our opinion No. 5598, rendered to you under date of April 29, 1926.)

The Nurses' Registration Act now requires an accredited school of nursing to give a course of instruction in theoretical teaching and practical work, covering not less than thirty-six months. Prior to the 1935 amendment to Section 4, an equivalent course of only twenty-eight months was required.

By the use of the conjunction "and," it would appear that the legislature intended such practical and theoretical work to cover the entire required period.

Particularly would this seem to be the case in the light of the preliminary language of Section 4, which requires applicants for examination to have not less than the required minimum instruction (either twenty-eight or thirty-six months) "in the actual care of medical, surgical, obstetrical patients and sick children."

This law was enacted in 1913 and contemporaneous regulations promulgated by the State Board of Public Health indicate that department's view of the law to be the same as is herein set forth. Requirement II, Section D, Subdivision 5 of Requirements of Accredited Schools of Nursing provides:

> "Students must be under instruction immediately on entrance to school. Instruction in the preparatory period shall be completed before the student begins the work of the next period. Students shall be on duty in the hospital for not more than four hours daily during the preparatory period of four months."

If you determine, in applying the legislative yardsticks referred to, that students registered in a nursing course in said universities before September 15, 1935, matriculated in "an accredited nursing school," as in said Act defined, it must follow that they come within the twenty-eight months' period of training which was referred to in the section before its amendment.

You further ask whether a student could qualify as a twenty-eight months' applicant for examination, which student, prior to September 15, 1935, had matriculated in a university giving a course of instruction of the character described by you, but who had not by said date completed that portion of the course given on the campus.

The answer to the first question makes unnecessary the answer to the second.

Very truly yours,

U. S. Webb,
Attorney-General.

By Lionel Browne,
Deputy.

SPECIAL ARTICLES

STANDARDS SET BY SOUTHERN CALIFORNIA SEWAGE TREATMENT PLANTS *

Southern California has inaugurated several procedures in both water treatment and sewage treatment which are new, at least in California. For example, there is the color problem in the deep wells at Wilmington, which is dealt with most successfully by an original scheme of color removal, involving prechlorination, ferric chlorid precipitation and rapid sand filtration. The American States Water Service Company has made varied, ingenious and successful use of sand and carbon filters, and of super and dechlorination of well waters in the Culver City-Lennox district where extremely troublesome fungus growths and hydrogen sulphid have come on as water tables lowered. Beverly Hills has set a record for ornateness and completeness of two water filtration and softening plants dealing with a similar problem and with hardness and addition. Imperial Valley should also be mentioned for at least two daring and quite successful water filtration plants dealing with the highly turbid Colorado River water. And of course the standards of safety and laboratory control of water supplies are especially high in the south, thanks to the several full time health departments and extent of chlorination of water supplies. No one place in California has approached Los Angeles in the perfection of water chlorination and laboratory control of the system.

In the field of sewage disposal, a number of devices and schemes got their introduction here. For example, the joint handling of sewage disposal on a large scale, such that four sewage treatment works serve some thirty-four cities; in Los Angeles the first use of fine sewage screens and the first use of incineration for the screenings; the development of two-stage sludge digestion by Los Angeles County sanitation districts; the largest instances of the application of chlorin in arresting odor production in sewers, by these same districts and by the Orange County cities; at Newport the first application of chlorinated iron for odor control; and at Whittier, the first use of preaeration in odor control. For over ten years the Pasadena sewage treatment plant has been known throughout the country as a proving ground of several new ideas in sewage treatment, including sludge conditioning and filtering, reclamation of sludge for fertilizer by kiln drying, grease removal by aeration and more recently, the only large scale heat exchange incinerator in the country for destroying the odors in the kiln gases.

---

* By C. G. Gillespie, Chief, Bureau of Sanitary Engineering, Berkeley.

Prepared for eighth annual session, Institute of Government, University of Southern California, June 15-19, 1936.

In a sense, southern California has shown a conspicuous alertness in the field of sanitation and health protection and there are some definite trends or standards in such matters as the large amount of laboratory control of water supplies, perfection of water chlorination, cleanliness of mountain streams, cleanliness of beaches, odor control in sewers and sewage treatment, and great activity in building sewerage works. In the last twenty years thirty-three high grade plants have been built in the south out of ninety in the state. These thirty-three plants serve forty-seven places, or about half the cities in the state having high grade sewage works. Thirty-seven "lower grade" plants have been built in the south, and close to one hundred elsewhere in the state. But these thirty-seven plants serve fifty-two places. The south has been particularly active in establishing new sewer systems. Sixty-one new sewer systems have gone in since 1915, contrasted with eighty-two for the rest of the state.

There is an unmistaken sensitiveness to sewage and sewage pollution, particularly within the reaches of the metropolitan area of Los Angeles, including Orange County and the mountains and beaches, perhaps because the same people flock to them for outdoor recreation. In the outlying counties of the south this same degree of interest is not so noticeable and, as elsewhere in the state, there is more of a tendency for people to become adjusted to matters of sewage disposal, and to live in peace with conditions, which in the metropolitan district have repeatedly led to fierce conflicts. For example, there were the sewer systems in Beverly Hills and Hollywood, now history; the sewer farm proposed for Anaheim, which was blocked by the incorporation of Stanton, a place that had no other earthly excuse for incorporation; similarly, the incorporation of West Covina and later the annexation of more territory to block the city of Covina in not one, but two sewage disposal projects; the incorporation of Monterey Park to block a sewer farm for Pasadena in the Monterey Park hills; later, the complaint of some 6,000 people in Alhambra against the sludge disposal at the then new activated sludge plant of Pasadena; the simultaneous nuisances from the various sewer farms of the Orange County cities which caused them to join in an outfall to the ocean; the blocking at every turn of local sewage disposal for Compton, Watts and Huntington Park, and which finally culminated in the White Point outfall to the ocean. However, the new sector of conflict then lay around San Pedro for many years. There were similar experiences in Glendale, Burbank, and in the beach cities from Hermosa to Santa Monica. The final answer was sewerage to the Los Angeles city system.

Just why this Los Angeles area should be so universally sewered and at the same time be so violently opposed to sewage disposal, forms an interesting subject upon which to muse. I have explained it all to my own satisfaction as the product of the boom days with skyrocketing of land values for subdivision and the tremendous influx of eastern and midwest people, naturally imbued with high ideas for better homes and better cities than those they had left behind. As a result, no subdivision could succeed without a sewer system and yet no subdivision could succeed with a sewage disposal plant next door. It made a difficult problem. Since subdivision was just around the corner for every square foot of land, it made sewage disposal almost impossible, both at inland plants and even at seaboard. Gradually plans have been perfected for handling the sewage of almost all of the metropolitan area in and around Los Angeles through outfalls to the ocean, and the processing of the sewage has been improved. Nearly ten million dollars are being expended for sewage treatment along the southern California coast in the interest of beach cleanliness. I believe the same higher standards of sewerage and sewage disposal should be anticipated in any area to which there is a strong tide of urban migration.

It may be questioned whether the present advances have strictly the fixedness implied by the word "standards." Looking back over the years, the efforts and advances seem more like the sorties of troops seeking to penetrate the enemy lines, first here, then there.

The first sewage treatment methods were septic tanks and sewer farms. Then two-story Imhoff tanks replaced the one-story septic tank idea. Ocean outfalls, with or without treatment tanks, replaced sewer farms wherever possible. Odors from the sewage treatment at these waterfront plants started a run on fine screens. Then as fine screens proved disappointing in the matter of odor prevention and failed to remove grease, or even all the solids, a few places went in for very long outfalls to permit ocean disposal of raw sewage. Structural difficulties with some of the outfalls, sentimental objection to the disposal of raw sewage in the ocean and an increasing premium placed on beaches, free even of the suspicion of a sewer, turned attention to the use of more inland sloughs and harbors, or to short ocean outfalls preceded by complete sewage treatment. Successful odor control at these plants was, of course, at the heart of this idea since adequate isolation was and is almost impossible. As noted elsewhere, the sorties into odor control are especially numerous.

The problem of unsightly and more or less odorous sludge beds at these ocean front locations first argued for greenhouse drying and more recently for digesting the sludge, then disposing of it through ocean outfalls under night time and other favorable conditions, so as to prevent its return to shore.

Since the bulk of the unsolved sewage disposal in the south is along the seacoast, where conditions in each place are much the same and extremely exacting, the effort should be to settle on the few guiding principles that would make sewer systems possible and sewage disposal tenable. Present features that seem to me to have permanent worth are: Centralizing plants to maximum degree; securing the best isolation of plant and outfall that is possible in each case; use of settling tanks and sludge digestion in each case; use of outfalls carefully engineered for foundation and stability of the entire line against most critical surf and ground swells, and designed to be immune against plugging by sand and to be of such additional length as may be needed for safe disposal of sludge and effluent so as to prevent any conspicuous sewage field and sewage contamination on shore. Chlorination to enhance the reputations for safety of the beaches is indicated, and also use of proven odor control measures in these plants. It must be set down that the beaches in name and in fact must be kept clean. The principal present sortieing will be into sound engineering of the outfall structures. The cities must devote their best talent without skimping on this cost, either in the preliminary surveys or in the actual construction.

Inland, the pattern of sewage disposal will probably continue along its present course with sewer farming the rule, accompanied by high grade plants in critical neighborhoods, and cheaper plants elsewhere.

Much debate as to method and place of sewage disposal will probably continue in the back country of the metropolitan area, which seems too far from the ocean for use of the county sanitary districts system with its ocean outfall. However, the State Board of Public Health, after many bitter hearings, still feels that such cities should stretch a point to finance connection in the centralized system. If they do not do this and resort to local disposal, the burden is heavy upon them to build and maintain as a pattern, odor free, high grade sewage treatment plants in the safest locations attainable. Along with this idea should go the procurement of enough land to ease the constant necessity for almost perfect odor control. Any odor control that is that severe is bound to require constant attendance of a high order and withal it may not be as dependable or as wise an investment as longer outfalls or even for more land for better isolation.

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 8, August, 1911

From Some Editorial Notes:

The American Medical Association Meeting.—The recent meeting of the American Medical Association in Los Angeles was a great success. And first let us extend to our colleagues in the South the sincerest congratulations and compliments upon the way in which they entertained the Association and cared for the comfort and the pleasure of all who attended the meeting. Especially to the Committee on Arrangements all credit and our thanks are due; every smallest detail had been thought of and arranged for the convenience of the visitor; there were no words but words of praise and astonishment, and our Eastern friends have gone away with a high opinion of California hospitality. . . .

* * *

Public Health.—The House of Delegates, at the Los Angeles session of the American Medical Association, passed a resolution commending the new Owen bill, Senate No. 1. This bill is a great improvement over the previous one introduced by Mr. Owen, and in all probability it, or a bill somewhat similar to it, will eventually be passed by the Congress. . . .

From an article on "Nasal Plastic, with Free Transplantation of Bone" by L. Eloesser, M. D., San Francisco.

Plastic surgery has, in the last few years, again begun to come into its own. The extension of our knowledge of the healing and of the growth of tissues, better insight into the relations of cell life to its environment, and the progress of constructive surgery that the last decade has brought have begun to bear fruit, and men are again beginning to push forward along the paths first opened by Dieffenbach, Nelaton, Langenbeck, and their compeers—paths where work had almost ceased these fifty years. . . .

From an article on "Intestinal Indigestion in Adults" by E. Schmoll, M. D., and Walter C. Alvarez, M. D., San Francisco.

For many years now, physiologists have been pointing out that the most powerful and varied ferments are those poured into the small intestine; that its absorbing surface is the largest part of the tract, and that intestinal digestion and absorption must be, if anything, more important than that which takes place in the stomach. When we remember, however, how slowly advances in the cognate sciences make their impress upon general medicine, it is not so surprising that we have to search carefully even in our latest books for any mention of intestinal digestion and its disturbances. . . .

From an article on "Dermatitis Venenata from Proprietary Hair Dye" by Ernest Dwight Chipman, M. D., San Francisco.

The frequent occurrence of a certain form of dermatitis having special characteristics and due to the use of a proprietary hair dye seems to call for further comment, even though similar cases have been previously reported. . . .

From an article on "The Early Diagnosis and the Prophylaxis of the Toxemia of Pregnancy" by Titian Coffey, M. D., Los Angeles.

The purpose of this paper is twofold: First, to show that the toxemia of pregnancy can be recognized early,

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By Charles B. Pinkham, M.D.
Secretary-Treasurer

BOARD PROCEEDINGS

At a regular meeting of the Board of Medical Examiners held in Native Sons Hall, San Francisco, July 6 to 9, inclusive, approximately 172 applicants wrote the examination, the larger proportion being graduates of medical colleges. There were also chiropodists and drugless practitioners.

The following changes were made in the status of licentiates of the Board of Medical Examiners:

Bayless, H. Gordon, Los Angeles. Cited on account of narcotic dereliction, was, on July 8, 1936, placed on probation for a period of five years, during which time he shall not have or apply for a narcotic permit or have narcotics in his possession. (Previous entry June, 1934.)

Belyea, John H., M. D., Los Molinos. Cited on charges of narcotic dereliction. License to practice suspended July 8, 1936, for a period of one year.

Coltrin, Francis D., M. D., Fullerton. Cited on the record of conviction of performing an illegal operation. License revoked July 8, 1936. (Previous entries June, 1925; April, May, June, August and November, 1935; May, 1936.)

Cruice, Leman Dow, M. D., La Mesa. His license to practice as a physician and surgeon, revoked July 12, 1934, was restored on July 6, 1936, and he was placed on probation for a period of five years, without permission to have or use narcotics in his practice. (Previous entry March, July and August, 1934.)

Gardner, Philip E., drugless practitioner, Los Angeles. Cited based upon aiding and abetting an unlicensed practitioner, was, on July 8, 1936, placed on probation for a period of five years.

Kay, Milton M., M. D., Shafter. Cited on narcotic dereliction, was, on July 8, 1936, placed on probation for a period of five years without narcotic possession or privileges. (Previous entry March, 1936.)

Kinsley, William L., M. D., San Diego. License was revoked February 4, 1931; restored July 6, 1936, and he was placed on probation for a period of five years without narcotic privileges. (Previous entries December, 1926; February, June, September, 1931; February, 1932.)

MacCracken, William B., M. D., Berkeley. License revoked July 8, 1936, based upon alleged illegal operation activities.

Olberg, Frederick H. C., M. D., Redding. Cited on alleged narcotic dereliction. Placed on probation July 8, 1936, for a period of five years without narcotic possession or privileges.

Payton, William B., M. D., Riverside. Cited for narcotic dereliction. Was on July 8, 1936, placed on probation for a period of five years without narcotic possession or privileges. (Previous entry, January, 1936.)

Rhodes, John McDonald, licensed chiropodist, Los Angeles. Cited on charges of practicing beyond the limitation of his certificate, was on July 7, 1936, placed on probation for a period of five years.

News

"The University of California officially confirmed today the retirement this year of Dr. Langley Porter, head of the University's Medical School. Doctor Porter has reached the retirement age. He is at present on a month's vacation. Dr. McKim Marriott, Dean of the Medical School of Washington University, St. Louis, has been selected to succeed Doctor Porter. Doctor Marriott will take his chair here at the beginning of the next university term." (San Francisco *News*, June 18, 1936.)

The Milbank Creamery Corporation, Milbank, S. D., called up to answer for an illegal shipment of butter, pleaded guilty and was fined $50. A portion of the butter shipped by this concern was found to contain mold and nondescript dirt, and the remainder of the shipment was below the legal standard for butterfat.

Other terminations of cases involving foods are reported as follows: L. Demartini Company, San Francisco, Calif., and Meyer Joe Laff, Los Angeles, Calif., moldy and wormy walnut meats, fines of $100 and $200, respectively; Uddo-Taormina Corporation, and Anthony A. Taormina, Donna, Texas, canned tomato paste containing mold, fines of $100 against each defendant (the corporation and its plant manager); Minster Canneries, Inc., Minster, Ohio, tomato puree containing mold, fine $25 and costs; Sterling H. Nelson Company, Salt Lake City, Utah, cabbage and cauliflower bearing poisonous spray residues, fine $26; Louis Markham, Des Moines, Iowa, potatoes in sacks represented as containing 100 pounds each, but in fact short of that amount, fine $10; and Western Macaroni Manufacturing Company, Salt Lake City, Utah, macaroni, spaghetti and similar products bearing no net weight statement and containing yellow coloring matter, fine $33.

The fine against the Feeders Supply and Manufacturing Company, Kansas City, Mo., reported by the Food and Drug Administration as $400, was reduced to $100 by the court when defense motion for a new trial was denied in the latter part of May.

In Federal District Court for the Southern District of New York, the Tilden Company, New Lebanon, N. Y., was fined $4,000 on June 30, the Administration reports. The fine, one of the largest ever imposed under the Federal Food and Drugs Act, was the penalty for a series of interstate shipments of pharma-

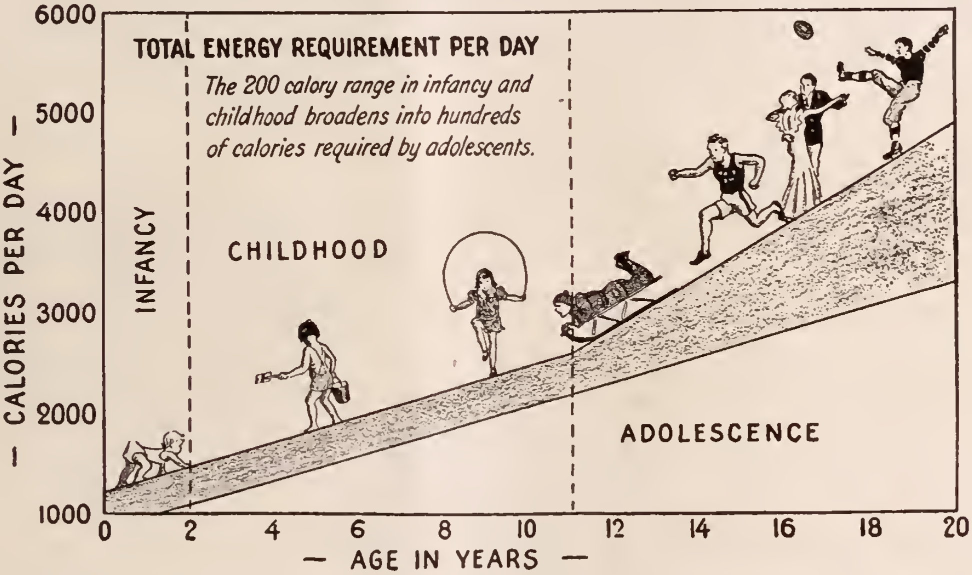
ADOLESCENT EXHAUSTION

relieved by

CALORIES *NOT* REST



NORMAL ADOLESCENT boys and girls frequently complain of fatigue. They feel weak and irritable; they show a diminished ability to concentrate; they are disinclined to work; they are physically inefficient.

Some of these symptoms are physiological manifestations of adolescent development. But on careful study many young folks do not consume enough food to provide them with the enormous energy requirements necessary during this transitional period. The symptoms are the consequence of undernutrition.

The graph reveals the sudden rise in caloric requirement during adolescence. Three hurried meals are usually insufficient to provide the tremendous caloric needs. Accessory meals, mid-morning and mid-afternoon, in certain instances, may be prescribed with advantage. And Karo added to foods and fluids can increase calories as needed. A tablespoon of Karo yields 60 calories. It consists of palatable dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Karo is well-tolerated, highly digestible, not readily fermentable, effectively utilized and inexpensive.

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. SJ8, 17 Battery Place, New York City.

POWELL *at* SUTTER

THE ALLERGIC NOSE

A LARGE number of allergic patients require the constant use of a vasoconstrictor to maintain the patency of the nasal passages. With prolonged use, most vasoconstrictors—such as ephedrine and epinephrine—not infrequently produce tolerance or atony.

Benzedrine Inhaler continues to give efficient shrinkage even when used over a prolonged period of time, and secondary returgescence following its application is reduced to a minimum.

CASE HISTORY: A. P., age 32, male, white. A plumber hypersensitive to dust; nasal mucosa chronically engorged. Observed at weekly intervals at Nose and Throat Clinic of a Philadelphia hospital.

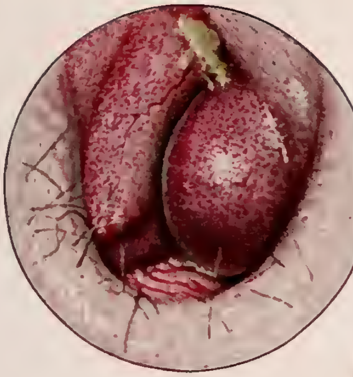

FIG. 1. Nov. 27. Nose in unshrunken state after 14 days of spraying twice daily with ephedrine, 1% in oil. Mucosa engorged, bluish, turgid and irritated; inferior turbinate blocking nostril. Marked tolerance to treatment had developed.

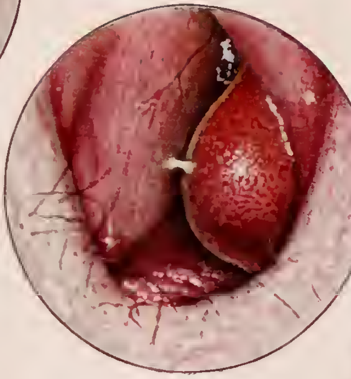

FIG. 2. Dec. 13. Nose in unshrunken state after 16 days treatment with Benzedrine Inhaler, three times daily. Engorgement reduced, tone good, irritation relieved. Note absence of atony.

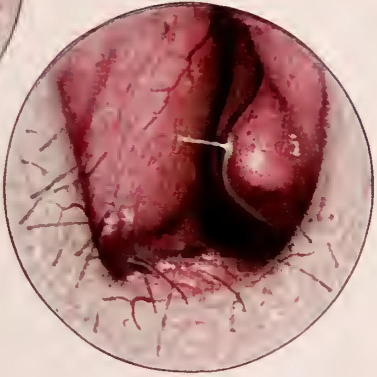

FIG. 3. Dec. 13. Nose in shrunken state seven minutes after application of Benzedrine Inhaler. High degree of shrinkage indicates no tolerance even after continued use.

BENZEDRINE INHALER

A Volatile Vasoconstrictor

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.

ESTABLISHED 1841

IN HAY FEVER
The Child Patient

The ease of application which makes Benzedrine Inhaler so useful with adults renders it even more helpful in treating the child hay fever patient. The vapor form—in addition to its greater effectiveness—overcomes the strenuous objections which children show to liquid inhalants as applied by drops, tampons or sprays.

Furthermore, the safety of Benzedrine Inhaler makes it especially suitable for pediatric use; it has been shown to have no deleterious effect even on the delicate cilia of the nose. Since it is volatile, it cannot disseminate a local infection by physical means—as it has been suggested that irrigations may do (Rucker: U.S. Pub. Health Reports, No. 30, 1927). Nor is there any oil to be aspirated and become a potential source of later trouble by accumulating in the lungs (Graef: Am. J. of Path., Vol. XI, No. 5, Sept. 1935).

Secondary reactions are "so infrequent and so mild as to be virtually negligible" (Scarano: Med. Record, Dec. 5, 1934), and, even in very young children, overstimulation or other undesirable reactions do not occur with proper dosage.

ceutical preparations found to vary markedly from the established legal standards and from their purported composition.

Two other cases involving substandard pharmaceuticals were terminated during June, resulting in a fine of $200 to the G. W. Carnrick Company, Newark, N. J., and one of $50 to the Cheplin Biological Laboratories, Inc., Syracuse, N. Y. In Cleveland, Ohio, a federal district judge overruled a demurrer to an information charging violation of the Food and Drugs Act in the shipment of a product labeled "Epsom Salt Compound Tablets." The manufacturer—Strong, Cobb & Co.—contended that the word "compound" in the name of the drug was a sufficient notification of the inclusion of powerful laxatives that the Administration contends the purchaser would not expect. The predominantly active ingredients in these tablets were shown by analysis to be phenolphthalein (a coal-tar laxative) and an extract of the laxative drug aloe. Although epsom salt was in fact present, the quantity of it fell far short of even a mild dose, the product actually depending for its effect upon the drug ingredients that were neither announced on the label nor indicated in the name of the preparation.

The report of the termination of one patent medicine case concludes the June statement of prosecutions involving drugs. Henry Lutzenkirchen, trading as the Ora-Noid Company, Chicago, Ill., dropped his intended contest of the government's case against him, based on a shipment of his product "Ora-Noid," and was fined $50 and costs. "Ora-Noid," half table salt and the remainder consisting of chalk, baking soda, magnesium and potassium sulphates and phosphates, flavored with an essential oil, was offered as a "complete oral prophylactic." Claims charged by the government to be false and fraudulent included: "It keeps the gums in condition; it strengthens all the tissues of the mouth, including the tongue, the palate, the throat, and the mucous membranes on the inside of the cheeks.

BUILDERS OF A COMMUNITY— and BUILDERS OF COMMUNITY HEALTH

There is a similarity between the physical building of a community—exemplified by the great San Francisco Bay Bridges, or the Los Angeles Aqueduct—and building a community's health.

Long before a foundation is firmly planted, or a tunnel dug, engineers are planning. Every steel strut, every pipe is built on paper first. Then comes actual construction and lasting years of utility and service.

Building a community's health requires planning, requires knowledge, and organizations and inspired men who see to it that the performance of their share in this complex ideal of health building is right.

Golden State Company is not unjustly proud of the part it has played in building the community health of California cities. Long before general practice made common the things which have brought the California dairy industry to its high state, Golden State aimed for and achieved most of those now common rules of sanitation and safety. Today, no less than at any time during the past third of a century, Golden State Company is still at the business of continuing its place as leader of the California dairy industry.

The complete story would take hours in the telling. Sufficient for the moment is the statement: "For More Than Thirty Years, Building Community Health."

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPHENAMINE
SQUIBB
ARSPHENAMINE
IODOBISMITOL
SALIGENIN

A factor of

decisive importance

in the treatment

of syphilis

"...One factor of decisive importance to the success of the method of treatment [of early syphilis] is the *regular steadiness* of its administration." Thus the report* made under the auspices of the Health Organization of the League of Nations following a study of 13,198 cases of syphilis stresses the importance of continuous treatment with an arsenical plus a heavy metal.

For the treatment of syphilis, two products by Squibb are worthy of note—Iodobismitol with Saligenin, and Neoarsphenamine. Iodobismitol with Saligenin is a distinctive anti-syphilitic bismuth preparation in that it presents bismuth in anionic (electro-negative) form. It is a propylene glycol solution containing 6% sodium iodobismuthite, 12% sodium iodide and 4% saligenin (a local anesthetic).

Iodobismitol with Saligenin has been shown by repeated clinical and laboratory studies to be rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated in both early and late syphilis.

Neoarsphenamine Squibb is readily and rapidly soluble and possesses uniformly high spirocheticidal power and low toxicity. Arsphenamine and Sulpharsphenamine are also available under the Squibb label.

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M.D., 490 Post Street, San Francisco, California. ✓ ✓ ✓

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

MICROSCOPES and OPHTHALMIC LENSES

In the great medical laboratories of the world, the name of Bausch & Lomb is held in great respect. Technicians and research workers know that the Bausch & Lomb signature on a microscope or other scientific instrument is a guarantee of excellence of design and precision of manufacture — without which many of the great achievements of medical science would have been impossible. And the same high scientific integrity behind the research microscope is reflected in Bausch & Lomb products for the correction of defective vision.

A thorough knowledge of optical theory and the procedure of modern refraction is behind the design of all Bausch & Lomb ophthalmic lenses.

The combination of Riggs craftsmanship with Bausch & Lomb materials offers a Prescription Service in keeping with ophthalmological practice of today.

Edwin L. Bruck, Secretary of Section on General Medicine, ex officio
John M. Schmoele, Secretary of Section on General Surgery, ex officio
Frederick C. Warnshuis (Chairman), ex officio

Committee on Public Relations

The Committee on Public Relations consists of the chairmen of the following standing committees and of certain general officers of the Association, all serving ex officio. The chairman of the committee is Charles A. Dukes, the secretary is Frederick C. Warnshuis. The director of the Department of Public Relations is Frederick C. Warnshuis. The chairman of the Committee on Public Relations is ex officio a member of the Council.

Fred B. Clarke	Chair., Com. on Health and Public Instruction
Daniel Crosby	Chair., Com. on Hospitals, Dispensaries, Clinics
Morton R. Gibbons	Chair., Com. on Industrial Practice
E. Vincent Askey	Chair., Com. on Membership and Organization
John H. Graves	Chair., Com. on Medical Economics
Junius B. Harris	Chair., Com. on Public Policy and Legislation
Charles A. Dukes	Chair., Cancer Commission
Clarence G. Toland	Chair., Com. on Postgraduate Activities
Edward M. Pallette	President of Califorina Medical Association
Howard Morrow	President-elect
Frederick C. Warnshuis	Secretary-Treasurer

Communications for the Public Relations Department should be addressed to the Director, Frederick C. Warnshuis, M. D., Room 2004, 450 Sutter Street, San Francisco.

Cancer Commission

Charles A. Dukes (Chairman)	Oakland	1937
Lyell C. Kinney (Vice-Chairman)	San Diego	1937
Alson R. Kilgore (Secretary)	San Francisco	1937
Orville Meland (Sec'y for Southern Section)	Los Angeles	1938
A. Herman Zeiler	Los Angeles	1938
Gertrude Moore	Oakland	1938
Harold Brunn	San Francisco	1939
Henry J. Ullmann	Santa Barbara	1939
Clarence G. Toland	Los Angeles	1939

Communications for the Cancer Commission should be addressed to the secretary, A. R. Kilgore, M. D., Room 2004, 450 Sutter Street, San Francisco.

(Roster lists of officers of scientific sections, component county societies, Woman's Auxiliary, A. M. A. delegates, special committees, etc., are continued on advertising pages 4 and 6.)

SOUTHERN SIERRAS SANATORIUM

C. E. Atkinson, M. D. . . . . *Medical Director*

SOUTHERN SIERRAS SANATORIUM
BANNING, CALIFORNIA

For Tuberculosis and Allied Affections

Has established and maintained a reputation, both among physicians and patients, for service and satisfaction.

Doctor: Send your next patient here, and you may feel assured not only that he will receive maximum benefit from his sojourn, but he will be grateful and will thank you for sending him to

SOUTHERN SIERRAS SANATORIUM

Western Electric

Electrical Stethoscope

- Loudness of heart and respiratory sounds can be increased about 100 times the intensity obtained with an acoustical stethoscope.
- Contains a filter circuit which isolates and accentuates murmur sounds.
- Particularly valuable for examining thick-chested patients.
- Useful in obstetrical fields for detecting foetal heart sounds.
- Indispensable to doctors with impaired hearing.
- Small, light-weight—comparable in size to doctor's instrument bag.
- Price—$116.00.

AVAILABLE THROUGH ALL PHARMACIES

EMMENIN

The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.

Manufactured by
Ayerst, McKenna & Harrison
(United States) Limited
Biological and Pharmaceutical Chemists
ROUSES POINT NEW YORK

Available in liquid form in original 4-ounce bottles.

BROEMMEL LABORATORIES
SAN FRANCISCO

The Physiological Treatment of Hay Fever.—It is now widely known that hay fever is due to the hypersensibility of the patient toward one or more foreign proteins, generally those of the pollens of neglected and useless weeds. Therefore, this fact must be kept in mind in the treatment of this disease. The pestiferous pollens are usually present in all parts of the United States between June 1 and September 1. They are present in the atmosphere, being wind-blown, the patient inhaling them into the nose. The pollens adhere to the sensitive and moist mucous membranes, and if they are allowed to remain and penetrate the surface, soon set up an irritation and inflammatory condition of the terminal nerve filaments, which quickly spread widely through the air passages.

In order to prevent the development and liberation of the poisonous proteins of the pollens, many physicians prescribe irrigation of the nasal channel from one to several times a day, thus washing them out as fast as they accumulate.

This cleansing process is easily and comfortably accomplished by the Nichols nasal syphon, about which further information will be found monthly in our advertising pages, which suggests itself as a safe and sure device, owing to its unique suction action. In fact, whatever treatment is prescribed, the device will prove an additional aid, inasmuch as it dissolves and draws out the pollen carrying secretions by irrigation.

After each irrigation, it is recommended that a bland oil should be used with an atomizer. This acts as a prophylactic, as it covers the membranes with an oil coating which prevents the pollens from adhering to them and starting the irritation.

We demand of men that they follow the herd; we suspect them if they express doubts of the tradition.—Laski.

Dr. Charles H. Mayo said: "The public knows less of medicine than of any other science."

Innervation of nasal turbinates and septum

Relief
THROUGHOUT ENTIRE CONGESTION PERIOD

NEO-SYNEPHRIN
HYDROCHLORIDE
(levo-meta-methylaminoethanolphenol hydrochloride)

In hay fever, allergic rhinitis, there is a definite advantage in using a vaso-constrictive agent which will relieve congestion quickly, without sting, and without loss of effectiveness under repeated applications.

Neo-Synephrin possesses definite advantages as a vaso-constrictive agent. It is less toxic in therapeutic doses than epinephrine or ephedrine, untoward systemic symptoms are diminished, and it is without sting at the point of application.

Neo-Synephrin is supplied in the forms of Solution, Emulsion and Jelly, so that the physician can select the product best suited to the needs of the case under treatment.

DOSAGE FORMS

SOLUTION
¼% and 1%
(1-oz. bottles)

EMULSION
¼%
(1-oz. bottles)

JELLY
½%
(In collapsible tubes with nasal applicator)

CO-OPERATE WITH YOUR ADVERTISERS

California and Western Medicine, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention California and Western Medicine.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this Journal to members and readers.

A SERVICE AGENCY—FOR READERS

The Journal of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in California and Western Medicine, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. California and Western Medicine and the A. M. A. Service Bureau desire to serve *you*.

THE NEW YORK POLYCLINIC
MEDICAL SCHOOL AND HOSPITAL
(Organized 1881)
(The Pioneer Post-Graduate Medical Institution in America)

Obstetrics and Gynecology

A full-time course. In Obstetrics: lectures; prenatal clinics; witnessing normal and operative deliveries; operative obstetrics (manikin). Gynecology: lectures; touch clinics; witnessing operations; examination of patients, pre-operatively; follow-up in wards post-operatively. Obstetrical and Gynecological pathology. Regional anesthesia (cadaver). Attendance at conferences in Obstetrics and Gynecology. Operative Gynecology on the Cadaver.

UROLOGY

- Surgical Anatomy
- Urologic Operations
- Diagnosis and Office Treatment
- Regional Anesthesia
- Proctology
- Neurology
- Cystoscopy and Endoscopy
- Dermatology and Syphilology
- Diathermy
- Pathology
- Roentgenology
- Operative Urology (cadaver)

345 West 50th Street, New York City

SUMMER COURSE IN
OPERATIVE SURGERY OF THE ABDOMEN
SEPTEMBER 22 to 30, 1936

Especial attention will be given to the latest development in the surgery of the Stomach, Gall-Bladder, Intestines, Colon, and Rectum. A brief review will be given of surgical anatomy of the various regions, with demonstration on carefully dissected cadavers. The work will consist of lectures, laboratory work on cadavers and fresh human material, and demonstrations and assisting on the living. Fee, $125.

SAN FRANCISCO POLYCLINIC AND POSTGRADUATE COLLEGE

Antivenin.—Concurrent with the reports of more than six hundred persons being bitten by the black widow spider, with a mortality record of forty, comes the announcement that E. R. Squibb & Sons are now supplying Antivenin (Anti-Black Widow Spider Serum). Widespread professional interest has been shown in methods of treating these bites, especially with the steady increase in the number of cases reported from southern, southwestern, and western sections of the United States.

Antivenin is prepared by the hyperimmunization of sheep with repeated doses of venom from the black widow spider. The serum is standardized by determining its neutralizing effect when mixtures of it with venom are injected into young rats. Clinical reports upon this important product, as well as information as to dosage and administration, are contained in literature supplied by E. R. Squibb & Sons upon request.

Antivenin is available in ampoules of sufficient content to permit the withdrawal and administration of 10 cubic centimeters of the serum.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE
(In affiliation with Cook County Hospital)
Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses; Intensive Two Weeks' Course starting October 5.

SURGERY—General Course, One, Two, Three and Six Months; Intensive Course, Surgical Technique every two weeks; Special Courses.

GYNECOLOGY—Three Months' Course, Intensive Two Weeks' Course, starting September 21 and October 19.

FRACTURES AND TRAUMATIC SURGERY—Informal Practical Course; Intensive Ten-Day Course starting October 5.

EAR, NOSE AND THROAT — Informal Course, Personal Courses; Intensive Two Weeks' Course starting October 5.

OPHTHALMOLOGY—Intensive Two Weeks' Course starting October 19.

UROLOGY—General Course Two Months; Intensive Course Two Weeks; Special Courses.

CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

General, Intensive and Special Courses in Obstetrics, Pediatrics, Tuberculosis, Roentgenology, Electrocardiography, Dermatology and Syphilology, Pathology, Neurology, Topographical and Surgical Anatomy, Physical Therapy, Gastro-Enterology, Allergy, Rectal Diseases, and Varicose Veins.

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL
Address: Registrar, 427 South Honore Street, Chicago, Ill.

The modern dietitian allows us to eat about what we will provided the vitamins are not excluded. Similar counsel may be given to the lover of books. Read what you like—newspapers and magazines, the novel and biography, history and technical books—but include somewhere in your reading regimen the vitamins of poetry, essays, and the drama.

The methods of quackery are merely a theft from the most ancient phases of folk-medicine.—Sudhoff.

CLASSIFIED ADVERTISEMENTS

Rates for these insertions are $4 for fifty words or less; additional words 5 cents each.

COACHING FOR STATE BOARDS—MEDICAL AND Dental. Arthur H. White, M. D., Suite 1005, Flood Building, San Francisco.

WANTED—COMPETENT YOUNG EYE, EAR, NOSE AND throat man. Give full particulars as to qualifications, experience, references, health, nationality, religion, stature, and salary expected. Send recent photograph. Address, Box 910, California and Western Medicine, 450 Sutter Street, San Francisco.

FOR SALE—VILLAGE AND COUNTRY PRACTICE IN Central California. Prosperous, irrigated country—dairy, fruit, grain. Good class American people. Large territory. Nearest competition thirteen miles. Very little to sell. Address, Box 900, California and Western Medicine, 450 Sutter Street, San Francisco.

WANTED—YOUNG WOMAN LABORATORY TECHNIcian experienced in all types of laboratory procedures. Salary $100 month and maintenance. Address, 1234 S Street, Fresno, California.

POSITIONS OPEN—THE MEDICAL BUREAU NEEDS California licentiates for the following: (a) Directorship, department of radiology, fairly large hospital; (b) industrial appointment, young man, experience in industrial work required; (c) general residency, $100, maintenance; (d) associate in eye, ear, nose and throat practice; (e) general practitioner, group appointment; some experience in private practice required; entrance stipend, probably $300. For further information write The Medical Bureau (M. Burneice Larson, Director), Top Floor, Pittsfield Building, Chicago.

SITUATION WANTED—WELL-TRAINED YOUNG PHYsician desires connection permitting him to specialize in medicine; B. S., M. S., M. D., leading schools; two-year internship, large teaching hospital; two years assistant to prominent internist; splendid personal qualifications; hard worker. No. 10, Medical Bureau, Pittsfield Building, Chicago.

Health Insurance.—"For the past three years, we have been studying and discussing various forms of health service. It is time for us to do something more than merely talk about it. We must look into the future and decide on a course of action.

"The problem of state dentistry is steadily assuming greater importance. Public interest has been increased by the debates on the subject in the public and parochial schools. We have this problem to meet. We are all agreed that the plan followed by the British is not for us."

"Little more need be said about the English plan, since we have already been supplied with a great deal of information as to how it is operating. The weakness of the plan, it is generally agreed, is that it supplies the actual dental services to the patients. This necessitates fixed fees and many rules, which are found to be against the best interests of patients as well as the progress of dentistry."

"I also visited Europe in 1935, with Doctor Casto, then president of this organization, and Doctor Wherry, a recent past president, and we observed sickness insurance plans as they were operating in leading European countries at that time.

"Only one conclusion could be reached as a result of our observations: The European plans are not adapted to the situation in our country. Conditions here are entirely different. Moreover, these plans have not offered a satisfactory solution even there, but give rise to new problems.

"The standards of dental practice that we have developed give American dentistry a preëminent position in the world today. We must make every effort to prevent the adoption of any plan for health insurance practice or a new economics for dentistry that would endanger these standards." (From President Winter's address at the recent annual session of the American Dental Association in San Francisco.)

NUTRI-AD
ARTHROPHYLL
(6)

A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL (6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL (6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

The author has succeeded in covering his subject in a manner that will enable the practitioner to gain sound information upon endocrinology and enable him to apply intelligent advice in his daily practice. This text must find its place in the library of every progressive physician and surgeon.

Williams' Obstetrics. By H. J. Stander, M. D., Cornell University. Cloth. Pp. 1269. Seventh edition. Price, $10. D. Appleton Century Company, New York.

The original sixth edition text was completed and published by Doctor Williams in 1931. The present editor has brought this standard up to date and causes it to remain as a recognized authority and dependable consultant.

Toxicology—The Effects of Poisons. By Frank P. Underhill, Ph. D., Yale University. Third edition. Cloth. Pp. 325. Price, $2.50. P. Blakiston's Sons & Company.

This is a short concise description of the effects of poisons upon organisms. It will be found to be a dependable reference guide. Symptoms are given and the treatment is in accord with present-day knowledge.

Vascular Disorders of the Limbs. By Sir Thomas Lewis, University College Hospital, London. Cloth. Pp. 107. Price, $2. The Macmillan Company, New York.

A general description of our present information upon circulatory disturbances of the extremities. Nothing new is contributed.

Theory and Practice of Psychiatry. William S. Sadler, M. D. Cloth. Pp. 1224. Price, $10. C. V. Mosby Company, St. Louis.

The author presents his thirty years of experience in the field of psychiatry. This book should be helpful to the medical practitioner. It is most interestingly written. The field is well covered and consistent with the accepted principles. Medical men in general, as well as in special fields, may well devote some of their time to the reading and study of this text. They will be more competent practitioners, having done so.

Treatment in General Practice. Articles republished from the British Medical Journal. Cloth. Pp. 250. Price, $3.50. Paul B. Hoeber, Inc., New York.

This is an excellent idea. The contents consist of certain outstanding articles that appeared in the British Medical Journal from December, 1934, to July, 1935. They cover a limited but an important field of general medical practice, and should be helpful to the working doctor. The following are general subjects presented by thirty-five articles: respiratory tract, specific fevers, and cardiovascular diseases. The authors are recognized British clinicians.

Medical science never stays still. New knowledge must be applied at the bedside. The compilation will be helpful because it is practical and because it teaches and does not speculate. Practitioners will find it most helpful.

Human Genetics and Its Social Import. By S. J. Holmes, Professor of Zoölogy, University of California. Cloth. Pp. 414. Price, $3.50. McGray-Hill Book Company, 330 West Forty-second Street, New York.

Sociology and biology are interrelated very closely. It is upon that premise that the author writes the first edition of this text. Biological and sociological principles are well presented.

This presentation commands interest by reason of the discussion and references being imparted in logical sequence. With the knowledge acquired from careful reading of this text, the thinking individual is better able to contribute to the upbuilding of a sounder, healthier, social structure.

BOOK REVIEWS

(Continued from Preceding Page)

Heart Disease and Tuberculosis. By S. Adolphus Knopf, M. D. Pp. 105. Cloth. Price, $1.25. Livingston Press, Livingston, New York.

This is a brief recapitulation of important matters related to these two conditions. Medical, surgical, and social aspects are reviewed. Prophylactic and curative measures are cited. This monograph will be very helpful to all practitioners.

Disability Evaluation: The Principle of Treatment of Compensable Injuries. By Earl D. McBride, M. D. Pp. 623, with 364 illustrations. Cloth. Price, $8. J. B. Lippincott Company.

An entirely new book on a problem that has ever been a difficult one to all concerned with industrial surgery and disabilities arising from industrial and civil accidents. Following an accidental injury there is always a dispute between interested parties as to the extent, permanency and extent of functional damage, and the degree of incapacity sustained. The opinion appraisal has been more or less guesswork and has been influenced, sorry to say, by the employer or employees' quest, inspired by the counsel of both parties.

Gradually we have seen a tendency toward agreement of opinion based on a normal percentage rating of function, and extent of loss of function and incapacity likewise expressed in percentage.

This author has compiled the normal percentage function of a part. He presents the many injuries that can be sustained. He outlines acceptable treatment calculated to produce the best functional result. Permanent degrees of end-results are given and rated. The percentage of disability is computed.

As a result we have a fair, sound establishment of a basis upon which the damage done can be expressed.

The author has accomplished that which has long been desired—an intelligent method, an equitable way in which to estimate functional damages and incapacity resulting from an injury. For this he is to be congratulated.

DEFINITE POTENCY *means* DEFINITE RESPONSE

DIGIFOLINE "Ciba"

IMPORTANT Your patient now receives 50 Digifoline Tablets for the price formerly charged for 25.

In the employment of digitalis, the first rule is to know the strength of the preparation in terms of efficient response. Digifoline, "Ciba"—containing all the cardio-active glucosides of digitalis leaf, and free from inert or undesirable substances—is assayed by the Hatcher and Brody Method to assure uniformity. The ampule form of Digifoline, "Ciba", is suitable for intramuscular or intravenous injection, since it contains neither alcohol nor glycerin, thus eliminating irritation. Each tablet, each ampule, each c. c. of liquid equals one cat unit—or 1½ grains of high grade digitalis leaf.

TABLETS · LIQUID · AMPULES

CIBA COMPANY, INC., NEW YORK, N.Y.

This text must become a part of the reference library of every industrial surgeon and for all physicians called upon to give opinion evidence and testimony. It is one of the best additions to medical literature in recent years.

California Medical Association Cancer Commission Committee Studies. Paper. Price, 75 cents. Pp. 129. San Francisco: California Medical Association, 1936.

The California medical profession has been exceedingly active in the last few years in conducting effective educational campaigns among both the lay public and the profession. In 1931, the House of Delegates of the California Medical Association created a Cancer Commission as one of the prominent commissions of the Association. This small volume is the report for 1936. The presentation takes the form of a series of committee reports on various types of neoplasms made by groups of specialists. It is obvious from the technical form in which these papers are written that they are intended primarily for the medical profession. Different committees report on tumors from the various regions or organs, and the Radiological Committee makes some general recommendations as to the use and limitations of radiation therapy. Contradictions that still exist on many of the questions discussed in this interesting and valuable pamphlet are frankly indicated. Owing to the limitation of space, the discussion has, obviously, to be rather dogmatic, but where there are differences of opinion, attention is usually called to this fact. For example (on page 59) the Committee on Genito-Urinary Tumors states, as regards kidney neoplasms, that there is no value in preoperative treatment and recommends postoperative irradiation, but a footnote calls attention to the fact that there is a well-marked division of opinion on the subject and that some believe that preoperative treatment only delays surgery. One member is quoted as saying, "We have ample evidence of the value of preoperative radiation. . . . It is not unusual to see an operable malignancy entirely done away with so that the operation itself becomes unnecessary." However, the committee adds that "it is hoped that in time sufficient statistical end-result evidence will be available to settle these questions." It is well to acknowledge that there are

Time and Chance

Time and chance play an important role in discovery and invention. In the medical field, however, these factors can often be reduced by co-ordinating the work of physicians, chemists, biologists, and pharmacologists provided with suitable laboratory facilities. » » In the development of promising medical discoveries, the Lilly Research Laboratories and the associated large-scale production laboratories of Eli Lilly and Company provide investigators with the best known means for reducing time and eliminating chance.

Four CAPSULES, T. I. D.

The concentration of antianemic material in Pulvules 'Extralin' (Liver-Stomach Concentrate, Lilly) is suggested by comparing these capsules. The raw or cooked liver necessary to equal the blood regenerating effect of the Pulvules 'Extralin' would fill the larger capsules.

Pulvules 'Extralin' afford a method of oral treatment in pernicious anemia which is more agreeable to the patient than the ingestion of liver as such. Four pulvules (filled capsules), t. i. d., will produce satisfactory reticulocyte response in most cases. Pulvules 'Extralin' are effective, tasteless, and convenient.

Supplied through the drug trade in bottles of 84 and 500 pulvules.

BOOK REVIEWS

(Continued from Page 15)

still many problems in the therapy of cancer which are still not solved and that any dogmatism on the subject is absurd.

This valuable little book should have a very wide circulation among the profession outside California as well as in it, and other state medical organizations might well learn a lesson from what has been done in California.

The Eye and Its Diseases. By eighty-two international authorities. Edited by Conrad Berens, M. D., Ophthalmic Surgeon, Pathologist and Director of Research, New York Eye and Ear Infirmary; Special Consulting Ophthalmologist, Woman's Hospital; Consulting Ophthalmologist, Veterans' Administration Facility, New York; Lecturer in Ophthalmology, New York Eye and Ear Infirmary; Member of American Board of Ophthalmology; Member of the Society of Surgeons of Paris; Lieutenant-Colonel, Medical Reserve Corps, United States Army. Pp. 1254, with 436 illustrations, some in colors. Philadelphia and London: W. B. Saunders Company, 1936. Cloth. Price, $12 net.

This book represents the efforts of eighty-two international authorities, each an investigator in his special field. The text is complete and thorough. General practitioners will find it valuable.

A Modern Product

Of Proved Value in . . . the Endotoxic Infections

Edwenil, the polyvalent antibacterial agent, while comparatively new, has already been used so extensively that it has won the place of a leader in the treatment of the endotoxic infections such as the respiratory diseases, boils, measles, etc.

It is a stable, colloidal, protein-free (by the Biuret Test) solution for intramuscular injection.

Edwenil promptly raises resistance to the endotoxic infections but causes no detrimental reactions, either local or general. It can be used daily to advantage. Send for complete literature on

TWENTY-FIVE YEARS AGO

(Continued from Preceding Page)

of excitement and competition, and the result is a nervous system ruined in its developmental period, producing the neurotic child so commonly seen among all classes of humanity. . . .

California Association of Medical Milk Commissions: Proceedings of the Annual Meeting, held in Santa Barbara, April 18, 1911.—The meeting was called to order by Dr. T. C. McCleave at 2 p. m.

On motion, duly seconded, Dr. T. C. McCleave was appointed permanent chairman and Dr. M. E. Jaffa temporary secretary.

Doctor McCleave explained the purpose of the meeting to be the formation of a State Association by federation of existing milk commissions.

On motion of Doctor Kress, it was voted to form such an association.

On motion, duly seconded, a committee on organization was appointed, consisting of Doctors T. C. McCleave, G. S. Baker, and G. H. Kress. . . .

The report submitted by Doctor Kress for the said federation of milk commissions was as follows:

1. The name of the organization shall be the California State Association of Medical Milk Commissions. . . .

From an article on "Bovine Tuberculosis and Its Relation to the Public Health" by George S. Baker, Bureau of Animal Industry.

Whatever relationship there is between tuberculosis of the bovine and the public health exists from the fact that we are milk drinkers and meat eaters. Under our present civilization, the dairy cow plays a wonderfully important part in the development of the human family. . . .

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 304)

at 1115 McAllister. There they arrested Mr. and Mrs. Walter Swindell. In an adjoining flat at 1117 McAllister Street, the officers took into custody Mrs. Gertrude Bergeron, who was booked as a vagrant. Then they proceeded to 431 Ashbury Street, where they arrested Mrs. Minerva Geddes, Mrs. Rudolph Zoffell, William Zoffell, Raymond Zoffell, and Mrs. Raymond Brandt. Simultaneously with the arrest here, Inspector Harry Husted of the homicide squad reported he had taken into custody in San Diego two women alleged to be implicated in the state-wide ring. They were Laura Miner and Nedra Arden. Both were booked at San Diego en route here. Husted said the pair were caught in the act of performing an illegal operation. The arrests here were part of a police drive against an illegal operation ring growing out of the death of Mrs. Florence Alves, thirty-six, Redwood City, mother of two children. A sister of the dead woman testified during a coroner's inquest she had taken her sister to the 1115 McAllister Street address to arrange for the operation that assertedly caused her death. . . ." (San Francisco *Examiner*, July 17, 1936.) Records of the Board of Medical Examiners indicate the premises at 1115 McAllister Street were for several years occupied by Eugene F. West, M. D., deceased, who was frequently

Adequate treatment of Pernicious Anemia

WITH A MINIMUM OF INCONVENIENCE TO THE PATIENT MAY BE OBTAINED BY THE USE OF

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

THE CHOICE OF A LIVER EXTRACT for the treatment of pernicious anemia should depend primarily on the potency of the extract. Since treatment must be continued at definite intervals, it is also important to consider the discomfort caused by the injection of the extract.

The newest of the *Lederle* parenteral preparations, 1 cc. CONCENTRATED SOLUTION LIVER EXTRACT, has now had nearly two years of clinical use. With this preparation it is possible to effectively treat pernicious anemia with a minimum of inconvenience to the patient.

Available only in boxes of 3 vials—each containing, in a volume of one cubic centimeter, active substance obtained from 100 grams of liver.

Carry the patient through the crisis with RESTFUL SLEEP..

SLEEP is important for the favorable outcome of operative procedure—of serious disease and of certain mental and nervous conditions. Ipral Sodium has been used to advantage in producing a sound sleep closely resembling the normal, from which the patient awakens generally calm and refreshed.

Ipral Sodium (sodium ethylisopropylbarbiturate) is a safe, effective sedative which is readily absorbed and rapidly eliminated. With proper attention to the dosage, undesirable cumulative effects may be avoided. No untoward organic or systemic effects have been observed when given in therapeutic doses. Ipral Sodium is supplied in ¾-gr. tablets as a sedative; in 2-gr. tablets as sedative and hypnotic; and in 4-gr. tablets for pre-anesthetic medication. Ipral Sodium 2 gr. is also available in capsule form —in bottles of 100 and 1000.

Ipral Calcium (calcium ethylisopropylbarbiturate) is supplied in 2-gr. tablets for use as sedative and hypnotic.

Tablets Ipral Aminopyrine (2 gr. Ipral, 2.33 gr. Aminopyrine Squibb) provide both analgesic and sedative actions.

These preparations are supplied in bottles of 100 and 1000 tablets. For descriptive literature address Professional Service Department, 745 Fifth Ave., New York.

LIVERMORE SANITARIUM

The Hydropathic Department devoted to the treatment of general diseases excluding surgical and acute infectious cases. Special attention given functional and organic nervous diseases. A well equipped clinical laboratory and modern X-ray Department are in use for diagnosis.

The Cottage Department (for mental patients) has its own facilities for hydropathic and other treatments. It consists of small cottages with homelike surroundings, permitting the segregation of patients in accordance with the type of psychosis. Also bungalows for individual patients, offering the highest class of accommodation with privacy and comfort.

GENERAL FEATURES

1. Climatic advantages not excelled in United States. Beautiful grounds and attractive surrounding country.
2. Indoor and outdoor gymnastics under the charge of an athletic director. An excellent Occupational Department.
3. A resident medical staff. A large and well trained nursing staff so that each patient is given careful individual attention.

specialists who have victimized several aged persons in southern and central California in recent weeks. . . . Belief that the swindlers are headed into northern California was expressed by Los Angeles authorities, who stated the four had been traced into several rural communities in the central valley areas." (Santa Rosa *Press-Democrat*, July 8, 1936.)

Ten persons awaiting trial here October 13 in connection with a coast-wide illegal operations ring received another blow from the law yesterday. They were indicted by the Grand Jury in Los Angeles for asserted operations there and in Hollywood and Long Beach during the past three years, according to Associated Press. . . . The ten indicted, as announced by Vernon Ferguson, Deputy District Attorney in Los Angeles, were: R. L. Rankin, Medical Acceptance Corporation head; Doctors G. E. Watts, Valentine St. John, and H. L. Houston; William A. Byrne, former State Medical Board investigator; John A. Creeth, G. O. Shinn, and three nurses, Bessie McCarthy, Grace Cole, and Lillian Wilson. In addition to them, Miss Jessie Radcliffe, receptionist, was indicted, Ferguson said. (San Francisco *Chronicle*, August 12, 1936.)

"Dr. H. C. Wallace, negro, a West Fresno doctor, today was arrested by Sergeant Rose and State Narcotic Inspectors Perry and Blonder on a charge of violating the State Narcotic Act. He was released on a $500 bond. . . . The doctor was arrested in 1928 on a charge of violation of the Federal Narcotic Act, and was given two years' probation. His right to issue narcotic prescriptions was revoked." (Press dispatch dated Fresno, August 7, 1936, printed in the San Francisco *Chronicle* (Fresno edition), August 8, 1936.)

"Prosecution of Dr. Malcolm Hoffman, physician and surgeon of 1735 Broadway, charged with administering a beating to a young San Francisco nurse was delayed yesterday when a request for a continuance was granted by Municipal Judge Daniel S. O'Brien. The young physician was charged with battery by his former fiancee, Miss Margaret Hecker, 767 Eleventh Avenue. Miss Hecker claimed she was taken in a car by Doctor Hoffman and two other men to Golden Gate Park, where the physician struck her three times while the other men looked on. They then left her there, she said. . . . Doctor Hoffman is also scheduled to appear August 19 for arraignment on the charge of performing an illegal operation. The physician was arrested by Inspector George Engler after a raid on an alleged abortion institute at 431 Ashbury Street." (San Francisco *Examiner*, August 13, 1936.)

Spastic Children CAN Be Helped!

We have a 7-year record of genuine improvement in even the most difficult cases of spastic children who have been sent to us for care. Miss Lillie Tucker, R. N., has specialized for years in the treatment and care of spastic children. We invite the personal investigation of parents and doctors at our attractive school-home above Burbank. Life is not all Milk and Rattles

Life is not as gentle to a tiny baby as it seems to be.

He comes into this world, never having breathed, never having eaten, never having digested food. Almost immediately, his little body must adjust itself to these vital functions.

If he is like most babies, he doubles his weight in the first few months; *triples* it in the first year. Every part of his body must make adjustments to accommodate this proportionately tremendous growth.

A new baby encounters disease-producing germs for the first time, and must build up resistance against them. If he does become ill, he is without the power to tell what the trouble is or where it lies. And when upset, he frequently is further endangered by the well-meant, but often harmful, suggestions of relatives and friends who "know *just* what to do."

Yes, infancy is so hazardous a period that, last year, the number of deaths among babies under one year of age was more than *three times* the number of deaths from automobile accidents.

The doctor is the one person equipped to give parents competent guidance through this dangerous period of a baby's life.

The doctor who sees the baby regularly can often detect sickness or physical trouble *in its early stages.* He can prescribe correct diet, proper hours of sleep, healthful and sensible handling of the habit problem. And he can start an important immunization program, to prevent such diseases as smallpox, diptheria, and whooping cough.

Enlisting the doctor's help—entrusting growth, diet, and general health to his supervision—is one of the most sensible precautions parents can take in those dangerous days of the child's first year.

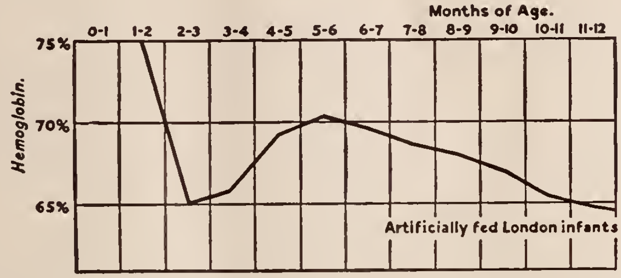
Nutritional Anemia in Infants



Hemoglobin level in the blood of infants of various ages. Note fall in hemoglobin, which is closely parallel to that of diminishing iron reserve in liver of average infant. Chart adapted from Mackay. It is possible to increase significantly the iron intake of the bottle-fed from birth by feeding Dextri-Maltose With Vitamin B in the milk formula. After the third month Pablum offers substantial amounts of iron for both breast- and bottle-fed babies.

Reasons for Early Pablum Feedings

1. The iron stored in the infant's liver at birth is rapidly depleted during the first months of life. (Mackay,[1] Elvehjem.[2])

2. During this period the infant's diet contains very little iron—1.44 mg. per day from the average bottle formulae of 20 ounces, or possibly 1.7 mg. per day from 28 ounces of breast milk. (Holt.[3])

For these reasons, and also because of the low hemoglobin values so frequent among pregnant and nursing mothers (Coons,[4] Galloway[5]), the pediatric trend is constantly toward the addition of iron-containing foods at an earlier age, as early as the third or fourth month. (Blatt,[6] Glazier,[7] Lynch[8].)

The Choice of the Iron-Containing Food

1. Many foods reputed to be high in iron actually add very few milligrams to the diet because much of the iron is lost in cooking or because the amount fed is necessarily small or because the food has a high percentage of water. Strained spinach, for instance, contains only 1 to 1.4 mg. of iron per 100 gm. (Bridges.[9])

2. To be effective, food iron should be in soluble form. Some foods fairly high in total iron are low in soluble iron. (Summerfeldt.[10])

3. **Pablum is high both in total iron (30 mg. per 100 gm.) and soluble iron (7.8 mg. per 100 gm.) and can be fed in significant amounts without digestive upsets as early as the third month, before the initial store of iron in the liver is depleted. Pablum also forms an iron-valuable addition to the diet of pregnant and nursing mothers.**

Pablum (Mead's Cereal thoroughly cooked and dried) consists of wheatmeal, oatmeal, cornmeal, wheat embryo, brewers' yeast, alfalfa leaf, beef bone, iron salt and sodium chloride.

Wilkinson from Milwaukee to Sacramento to face a charge of swindling about $10,000 from a Sacramento County rancher in a fake eye-cure scheme. The news of Wilkinson's arrest received here in a telegram late Saturday from Milwaukee postal authorities ended a five-year search by the sheriff's office. The case is being handled by Deputy Sheriff Ogle. The victims of the racket are Charles and Gottfried Zeh and Johanna Zeh of Antelope. Nearly five years ago they paid Wilkinson, known to them as Dr. J. P. Billingsley, Seattle eye specialist, about $10,000 to remove a cataract in Miss Zeh's eye. Wilkinson, after performing an operation on Miss Zeh's eye, sold her a 'radium belt' for eye treatment. Ogle said it merely was a leather contraption with a small battery attached which produced a mild electric shock. The Zehs paid $986 in cash for the operation and put up certified checks totaling $9,000 as deposits on the belt. About three years ago a Robert Cavenagh, identified by Miss Zeh as the man who took her the belt, was sentenced to a year in the city jail here as an accomplice in the scheme. Cavenagh was arrested in Los Angeles, and simultaneously Wilkinson was held in San Diego on a misdemeanor charge. Before Miss Zeh could reach San Diego to identify him, he escaped, forfeiting his bail. . . ." (Sacramento *Bee,* August 3, 1936.) An article dealing with the eyesight swindlers was published in the 1932 annual report of the Board of Medical Examiners, published in our 1933 directory.

A signed statement made to Inspector Joseph J. McCullough of the New York Board of Medical Examiners by Alfred Storm (New York County Penitentiary, K-64314, July 17, 1936), recently arrested in New York City on a charge of violation of the Medical Practice Act, revealed Storm as the dapper little Frenchman, also known as Peter O. LeRoux, who obtained employment in several hospitals throughout the United States, using the name and credentials of Alfred A. Hesse. Among the

institutions where he served as a physician was the San Joaquin County General Hospital. A history of this impostor appeared in the 1932 annual report of the Board of Medical Examiners, published in our 1933 directory.

Information recently came to the Board of Medical Examiners that an individual named "Dr." Holsted Hanson, assertedly claiming to be a retired surgeon, a Ph. D., a medical expert, etc., also claiming that an enormous fortune was coming to him from Denmark, recently located in San Diego. Our informant states that said individual has no college degree of any sort, is not a bacteriologist, and has not at any time been connected with the State Board of Health of New York. Holsted Hanson was featured in the Buffalo (New York) *Evening News*, Thursday, December 22, 1932, in an article headed "Holsted Hanson, Once Model for Marchand, in Jail Again—Self-Styled Bacteriologist Must Serve Six Months . . ." also in the Buffalo (New York) *Evening News*, Friday, June 23, 1933, in an article headed "Hanson's Activities Again Scrutinized—State Inspector Wants Picture Showing Swindle Posing in Operating Room." The Board of Medical Examiners would appreciate any information regarding Holsted Hanson.

The New American Medical Directory.—The fourteenth edition of the American Medical Directory has been completed and copies are now available for general distribution.

The directory, with nearly twenty-five hundred pages, is a vast storehouse of information. It contains not only the most complete list available of the physicians of the United States and its dependencies and of Canada, but much additional data which hospitals, libraries and various other

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M. D., 490 Post Street, San Francisco, California.

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

Mailing containers sent on request. Special delivery postage insures prompt, accurate service.

institutions, as well as individuals, will find useful and readily available. The directory is the only nation-wide register of physicians in which the extensive data on medical education, licensure, and society affiliations have been verified.

The 1936 edition contains 183,312 names, or 4,796 more than were in the previous edition issued in 1934. The names of 13,157 physicians have been added and 7,684 names have been removed because of death. More than 70,000 changes of address have been made, in addition to thousands of changes in society affiliations, teaching positions, specialties, and office hours.

In this edition, thirty-two states show an increase in the number of physicians; New York leads the list with 1,201, followed by California (369), Pennsylvania (281), New Jersey (262), and Massachusetts (249). A slight decrease in the number of physicians is shown in Missouri, Georgia, Kentucky, Tennessee, Oklahoma, Alabama, Indiana, South Dakota, Maine, Vermont, Mississippi, and New Hampshire. When the thousands of changes of location are analyzed they seem to show a noticeable migration of physicians to the larger towns in the south central states, a trend that was previously present also in some other sections of the country.

The first section of 221 pages in the new directory includes the constitution and by-laws of the American Medical Association, the Principles of Medical Ethics, and a list of meeting places of the annual sessions of the Association since the first one in 1847, with the names of the president installed during each meeting. In this section also are lists of the hospitals that are approved for intern training, the medical libraries, the medical journals published in the United States, Canada, the Philippine Islands and Puerto Rico, the names of medical officers of the various government services, the national organizations for the various specialties with the names of their members, the membership of the new examining boards for the specialties, the medical schools in the United States and Canada

minimizes scarring

A FEATURE OF
ANTI-PYREXOL

This most comfortable, and least troublesome dressing for burns may be depended upon to:

1. Relieve pain promptly.
2. Protect denuded areas.
3. Give antiseptic protection.
4. Combat toxemia.
5. Promote prompt healing.
6. Minimize scarring.

Anti-Pyrexol is available through surgical supply houses and drug jobbers in 2-oz. tubes, 1-lb., 5-lb., 10-lb. tins. For technical information address Mona E. Bettin (M. D.), Pathological Laboratories, Roosevelt Building, Los Angeles, or:

Not Advertised to Laity

(Continued from Preceding Page)

with a brief history of each, and the members of the National Board of Medical Examiners.

The second section is arranged by states. There is published under each state the Medical Practice Act, the members of the Board of Medical Examiners, members of the State Board of Health, county and city health officers, and officers of the state, district, and county medical societies. Following this is a list of 7,220 hospitals, sanatoriums and related institutions, arranged by towns, with the name, location, bed capacity, superintendent, and type of patients treated in each institution. Then, arranged by towns, comes the great list of physicians, giving the year of birth, school, year of graduation and license to practice, membership in the state society and special societies, professorships, and Fellowship in the American Medical Association. The home and office addresses and office hours also are given for physicians in towns of more than 10,000 population.

A new feature in this edition is a key letter showing that a physician has been certified as a specialist by an approved examining board. Several of these boards have been approved by the Council on Medical Education and Hospitals since the directory went to press. The next edition, therefore, will contain a more complete list of certified specialists. An especially interesting feature of the 1936 edition is the list of American physicians temporarily located in foreign countries.

The third section, of 525 pages, is an alphabetical index of the names of 183,312 physicians; and practically every name is followed by the name of the city and state, thus indicating where in the directory detailed information about the individual physician may be found.

The bringing to completion of the fourteenth edition of the American Medical Directory has been a monumental task, in the pursuance of which thousands of individuals, societies, licensing boards, medical colleges, and other organizations have coöperated. For their ready coöperation and assistance the American Medical Association is thankful and deeply appreciative.

WHAT'S A BIO-ASSAY?

Few patients have more than a vague idea what a bio-assay is . . . to say nothing of the equipment, controls and skill necessary for running one properly. While the physician naturally looks to the maker's ability and facilities for rigid bio-assaying in selecting a vitamin product, patients can't be expected to do the same. ● To make certain their patients obtain only a fully potent product whenever Vitamins A and D are indicated, many physicians make it a practice to write all their prescriptions for Haliver Oil with Viosterol and to specify *Abbott.* ● This original research product has behind it every safeguard and manufacturing method which could contribute to certainty of quality. Each lot of oil is bio-assayed under conditions permitting greatest possible accuracy. ● Prescribe routinely for growing children, pregnant and lactating mothers, and all other patients who require additional Vitamins A or D. At prescription pharmacies everywhere in tasteless 3-minim capsules in boxes of 25, 50, 100 and 250; in 10-cc. and 50-cc. vials.

Makers of Medicinal Products

Ephedrine Relieves Congestion

The local application of ephedrine to mucous membranes causes capillary contraction and reduces swelling. Relief of congestion in upper respiratory passages is prompt and well sustained.

For topical treatment:

Inhalant Ephedrine Compound, Lilly, containing aromatics.

Inhalant Ephedrine, Plain, Lilly, without aromatics.

Solution Ephedrine Sulfate, Lilly, and Solution Ephedrine Hydrochloride, Lilly.

These products and other ephedrine preparations for oral or parenteral use are supplied through the drug trade.

Subscription prices, $5 ($6 for foreign countries); single copies, 50 cents.

Volumes begin with the first of January and the first of July. Subscriptions may commence at any time.

Change of Address.—Request for change of address should give both the old and the new address. No change in any address on the mailing list will be made until such change is requested by county secretaries or by the member concerned.

Responsibility for Statements and Conclusions in Original Articles.—Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. It is aimed to permit authors to have as wide latitude as the general policy of the journal and the demands on its space may permit. The right to reduce or reject any article is always reserved.

Contributions—Exclusive Publication.—Articles are accepted for publication on condition that they are contributed solely to this journal.

Contributions—Length of Articles: Extra Costs.—Original articles should not exceed three and one-half pages in length. Authors who wish articles of greater length printed must pay extra costs involved. Illustrations in excess of amount allowed by the Council are also extra.

Leaflet Regarding Rules of Publication.—CALIFORNIA AND WESTERN MEDICINE has prepared a leaflet explaining its rules regarding publication. This leaflet gives suggestions on the preparation of manuscripts and of illustrations. It is suggested that contributors to this journal write to its office requesting a copy of this leaflet.

EDITORIALS†

ARE PHYSICIANS REMISS IN CIVIC RESPONSIBILITIES?

Physicians Reluctant to Become Legislators. It is to be regretted that so few physicians in the United States seek to serve their country in legislative halls. For this lack of civic interest and willingness to assume such responsibility, the medical profession is made to suffer, as witness in many commonwealths the numerous cultist examining boards, the recurring onslaughts on the standards of medical practice acts, the attacks upon legitimate public health activities, the efforts of antivivisectionists and similar well-meaning, but nothing-much-more, groups.

* * *

Next California Legislature Convenes in January, 1937.—The next California Legislature will convene in the first week of January, 1937, and we shall observe, as in years gone by, the introduction of probably five hundred or more bills, each of which, if enacted into law, may affect public health and medical practice interests. These measures, even now, are probably in their formative dress, their sponsors merely awaiting the outcome of the primary election on August 25 to determine which of the opposing candidates for each assembly and senatorial district shall be supported; so that election support then given, if coupled with victory in the final elections, in November, shall be rewarded with partisan advocacy of the proposed laws.

* * *

Medical Profession Can Take a Lesson From the Legal Profession.—As always, there will be a good representation in the legislature of the legal profession, whose younger and some older members find it worth the effort to be known as such. In addition, this year, as in the four years just passed, we may look for a rather substantial representation of citizens who are allied to some of the newer reform movements.

How beneficial, then, it would be if among the successful legislative candidates it were possible to note, as six or more assemblymen and three or more state senators, and in the federal legislative halls, as one or more congressmen from California, the names of those already honoring the medical profession!

---

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

* * *

Physicians Not in Active Practice Should Be More Active in Civic Matters.—Such a picture could easily be created, especially if some of the older members of the profession, whose means are such as to no longer demand their active practice, responded to the lure of civic duty and stood as candidates for these offices!

California, and other states as well, need in their legislative halls the knowledge and judgment which members of the medical profession can give, and more so than ever before in these years of social unrest.

* * *

County Medical Societies Should Also Be Alert to Civic Responsibilities. — Here and there, one is able to note signs of increased interest in matters of this kind on the part of organized medicine units. Take, for example, the action of the Board of Councilors of the Los Angeles County Medical Association in authorizing the appointment of a committee to form a class for physicians wishing to study methods of public speaking. That effort came from the experience of radio talks, it having been demonstrated that very few physicians know how to prepare and deliver an effective talk for a radio audience. The plan, for its evident value, is commended to the consideration of other component county medical societies.

* * *

Proposed Legislation to Be Studied.—As regards legislation to which the California Medical Association may give special attention in 1937, it need hardly be stated that the Council and the Committee on Public Policy and Legislation will make an earnest effort to consider most carefully all possible needs. In a general way, very little that is new is likely to be offered. If conclusions can be drawn from the experiences of former legislative sessions, it is probable that most effort will need to be directed against vicious public health legislation now in the forming, which will first come into the open at the end of January or perhaps even after the February recess.

Component county societies and individual members of the Association, therefore, are cautioned not to give endorsements or approval of legislative measures without first communicating with the Committee on Public Policy and Legislation, through the office of the Association Secretary. Embarrassing situations, and worse, will thus be avoided by observing this rule.

* * *

At the November Election, Support Only Legislative Candidates Who Hold Sound Views on Public Health. — By the time this issue of the official journal reaches its readers the primary election will have decided who are to be the opposing candidates. With that fact established, physicians, both as individuals and through their organized units, should learn the reaction of all nominees on sound public health measures, so that support in the November election may be given to the candidates who, in these matters at issue, can best serve the people.

QUALIFYING CERTIFICATE (BASIC SCIENCE) LEGISLATION

Tentative Draft of Qualifying Certificate Law Has Been Prepared.—In the last legislature, a tentative draft of a Qualifying Certificate law was introduced, more, however, to give notice that such a statute was seriously contemplated than with any thought to urge its passage. As was anticipated, the measure, in the form proposed, was generously amended in committee, where it remained until the legislature adjourned.

The Special Committee of the California Medical Association, to whose members have been delegated the study and drafting of a Qualifying Certificate law, has no intention at this time of presenting such a statute for the consideration of the 1937 California Legislature. That does not mean that other interests or individuals may not submit such a proposed law.

* * *

An Initiative Law Is Necessary. — As has been stated in the committee reports printed in the official journal, a Qualifying Certificate (Basic Science) law to be of any value in California—a state with multiple examining boards—must be made to include each of the healing-art boards already established, as well as others that may be established in the future. In view of the fact that California has three healing-art acts—the medical practice law, a legislative enactment; the osteopathic law, an initiative statute; and the chiropractic law, also an initiative measure—it is understandable why a Qualifying Certificate law must also be enacted by initiative vote of the electorate, if it is to be made to apply to the above groups. For a basic science law passed by the legislature could not be made to include either the osteopathic or chiropractic groups.

* * *

Initiative for Qualifying Certificate Law to Be Submitted in 1938.—For this reason the proposed Qualifying Certificate law must lie over for the regular state election in November, 1938. In the meantime, when opportunity arises, the advantages and need of such a law should be stressed before lay and professional groups.

It is not anticipated that the osteopathic licentiates will give serious opposition to such a measure, because that group is constantly raising its standards of admission and should have no serious objection to such a measure. It is to be hoped that the chiropractors who are licensed will also appreciate the advantages in such a law. Practitioners of all healing-art groups already licensed in California will come under the provisions of such a law, not through examination, but by registration of their certificates as licentiates. But every graduate, after the enactment of such a law, and prior to taking his healing-art examination for licensure, would be obliged to present a certificate from the Qualifying Certificate Board to show that he had successfully passed its examination.

* * *

Basic Elements of Proposed Qualifying Certificate Law.—The tentative provisions of the California Qualifying Certificate law, which has been outlined in previous issues of California and Western Medicine, have been designedly drafted in broad and liberal manner, with the basic thought in mind that it is not a quantitative amount of specified knowledge that is needed so much as that the applicant for the certificate shall have had cultural training of a certain standard, and that the examination shall be given by a liberal arts (non-healing art) board of undoubted scholastic ability and integrity, and free from all political influence. It is believed that the bill, as contemplated, will possess these requisites. Members of the profession who are interested are invited to send suggestions to the committee, whose members are listed in the Special Committees on advertising page 6 of each issue of the Journal.

"THE ATTACK ON GROUP MEDICINE"

"The Attack on Group Medicine," an Effusion by an "Advertising Man."—*The Nation*, a magazine known to a goodly number of Americans, in its issue for July 4 prints an article entitled, "The Attack on Group Medicine," by one James Rorty.

The author is not so well known as the publication for which he writes; but *The Nation*, in discussing the contributors to that number, on page 140, naïvely states:

> James Rorty concludes in this issue his series on medical politics in the United States. Formerly an advertising man, Mr. Rorty wrote the inside story of advertising in his book, "Our Master's Voice." . . .

* * *

This "Advertising Man" Thinks He Knows His Subject.—Read, now, some of the outpourings of this former advertising man who, in the language of his training, speaks dogmatically and otherwise concerning the medical profession and its constituted bodies of organization; reference to which article is made because it is an example of similar outpourings from propagandists inspired mostly by sources unknown.

The Borden Milk boycott of Chicago is dragged into the opening paragraphs, and the American Medical Association, and also its secretary, Dr. Olin West, and its journal editor, Dr. Morris Fishbein, are taken to task for not having made official pronouncements against the boycott. Read and ponder:

> Excellent! But did the American Medical Association officially and publicly repudiate the boycott at any time while it was in progress or since? It did not. Did Doctor Fishbein repudiate the boycott in the *Journal?* He did not.
>
> The plain fact is that in doing what they did the medical boycotters and slanderers were obeying the spirit, if not the letter, of policies which the American Medical Association has followed for many years—policies designed to defend and perpetuate a system of medical service and payment which is demonstrably obsolete and heartbreakingly destructive both of human health and medical idealism. Again and again, both officially and unofficially, the American Medical Association has used brass knuckles on the advocates of change in the organization of medical care wherever they showed their heads. As a result of this policy some of the best heads, both in and out of the medical profession, are bloody—but not noticeably bowed. Expulsion from his medical society, the loss of hospital and university appointments, public ostracism, and private slander—these are the penalties visited almost automatically upon nearly every doctor who attempts to rip off the nineteenth century swaddling clothes in which the rugged medical individualists would like to bind the huge potential resources of modern medicine.

Could statements such as these be clothed in sentences more ridiculous? Before Advertising Man Rorty rushed into print with such an onslaught, he might well have taken time to familiarize himself with the history of the American Medical Association and its long record of commendable service.

* * *

The Place Given to State and County Medical Associations.—Note the mental attitude of "former advertising man, Mr. Rorty," and how he vents his mind upon the constituent state associations and their component county societies:

> There is plenty of current evidence that the ruling hierarchies of the American Medical Association, including most of its state and county units, intend to obstruct and hamstring all attempts to set up voluntary group-practice and group-payment schemes of medical care, regardless of the demonstrated quality and economy of the service offered by such organizations. . . .

After commenting, too, on the Los Angeles and Dallas County Medical Societies proceedings, Mr. Rorty states that the American Medical Association Judicial Council

> . . . enunciated a new principle, now embodied in two clauses, 6 and 7, which have recently been added to the office code of ethics. Any group-practice organization is now ruled "unethical."
>
> 6. When the conditions of employment make it impossible to render adequate service to the patients.
>
> 7. When the contract, because of any of its provisions or practical results, is contrary to sound public policy.
>
> In practice this means that if the majority of the members of any county medical society decide that a clinic or group-practice organization is "against sound public policy" they can expel from their society the doctors associated with the clinic, and the Judicial Council of the American Medical Association will sustain them. What the American Medical Association is saying in effect is this: A group clinic may not solicit patients, directly or indirectly; may not underbid individual physicians to secure a contract; may not charge fees which, in the judgment of the competing individual members of the county medical society, are inadequate to secure good medical service; may not interfere with reasonable competition in a community; may not prevent free choice of a physician; may not set up conditions of employment which *in our judgment* make it impossible to render adequate service to patients. Finally, no group-practice organization may operate under a contract which because of any of its provisions or practical results is *in our judgment* contrary to sound public policy.
>
> This is the heart of the American Medical Association's 1936 policy with respect to the organization and distribution of medical care. Not even the United States Supreme Court has dared to assert such impudent claims to power over matters affecting the life and death of the American

people. True, the American Medical Association has no legal authority. It cannot prevent a physician from practicing nor can it stop a group clinic from operating. But it can and does implement its claim to authority by public excommunication and private ostracism and persecution. It has no police powers, but it can and does summon its medical squads and battalions to a holy war in defense of their own status, their own emoluments. It does this whenever the pressure of public need fires a group of progressive doctors with the determination to cast off the shackles of the American Medical Association's pocket-motivated "ethics" and attempt to give people decent medical care at a price they can afford to pay. There have been scores of such holy wars and they are all pretty much alike. Two recent examples will suffice to illustrate the customary strategy and tactics.

In similar fashion, in this "second of a series of four articles on medical politics," Layman Rorty continues on to discuss several medical-service groups which in his opinion have been unjustly disciplined by the county medical organizations of which they were members; his inference being, of course, that the members of the county societies were in each instance persecuting the offenders.

* * *

The Respective Backgrounds of Advertising Men and of Physicians.—It is not to be wondered at that a layman, with an advertising man's training and background such as that of Mr. Rorty should be unable to understand why physicians place a high value on conduct as a basis of membership in their county medical societies, and that when county society members as a whole, and almost without exception, object to a member or members inaugurating a form of medical service which somewhere in its make-up is motivated and associated with commercialism as a basic element, rather than by maintenance of high standards of professional service, these members of county societies are only giving expression to their individual selves as reflected in the aspirations that led them to enter a profession where service to human fellows, rather than acquirement of riches through trade or vocation, was to be the major element in their life careers.

* * *

The Advertising Man Needs More Training in Logic.—Mr. Rorty writes his story in first-class style—for that is what an advertising man must learn to do to emphasize the wares of his client; but he certainly draws broad and dogmatic deductions, with condemnation of almost the entire medical profession of the United States (for the American Medical Association has a membership of about 103,000 physicians), from some isolated instances which even if he were right—which we believe he is not—do not establish premises warranting such conclusions. And even if in one or two cases he were right, he might well remember the old rule in logic, not to draw general conclusions from special instances, which he seemingly has done, with literary results as noted above. Perhaps, it was the literary merit (!) that led the editors of *The Nation* to accept the article. If not that, then mayhap some of their special journalistic policies, which an inspection of their magazine quickly reveals.

ANNUAL REPORT OF THE ROCKEFELLER FOUNDATION FOR THE YEAR 1935

President Max Mason's Foreword.—Max Mason, retiring president of the Rockefeller Foundation, in the opening paragraphs of his foreword states:

> I have the honor to transmit herewith an account of the work of the Rockefeller Foundation for the period January 1, 1935 to December 31, 1935, including the reports of the secretary and the treasurer of the Foundation, the director of the International Health Division, and the directors for the Medical Sciences, the Natural Sciences, the Social Sciences, and the Humanities, and of the vice-president in charge of program in China.
>
> During the year the Foundation has continued its efforts in public health through the International Health Division. Financial assistance and the coöperation of its staff have supplemented governmental agencies in the training of public health personnel and in the control of disease, while the staff has continued its study of certain diseases in their environments, and also the laboratory research to which this study leads.

The detailed, but most modest outline of the activities of the Rockefeller Foundation for the year 1935, which follows, needed 479 pages to tell the story of altruistic and wise endeavor for betterment of the human race, to effect which this meritorious foundation stands sponsor.

* * *

How the Money Is Spent.—The funds available in the Foundation total $46,523,610.86.

Disbursements during the year amounted to $12,725,439.34. Members of the medical profession will be interested to note the nature of some of the fund allocations:

Medical sciences	$ 692,524.79
Public health	8,285.26
Nursing	511,242.73
Research programs	699,214.33

In the summary of expenditures in 1935 are mentioned activities such as:

UNIVERSITIES AND OTHER EDUCATIONAL INSTITUTIONS

Medical Science Education	
Cheeloo University, Tsinan, China	$ 4,168.75
China Medical Board, Inc., New York City	460,850.00
Chulalongkorn University, Bangkok, Siam	7,214.35
University of Brussels, Belgium	200,000.00
University of Colorado, School of Medicine	7,791.69
University of Montreal, Canada	12,500.00
	$ 692,524.79
Public Health Education	
Dalhousie University, Halifax, Canada	$ 8,285.26
Nursing Education, University of Toronto, Canada	8,238.18
Vanderbilt University, Nashville, Tenn.	500,000.00
Miscellaneous	3,004.55
	$ 511,242.73
Public Health	
Central Medical School for Native Medical Students, Suva, Fiji	$ 7,419.44
Regular program of the International Health Division in state and local health work, public health education, control and investigations of specific diseases	2,015,470.95
League of Nations Health Organizations, Geneva, Switzerland	105,220.56

National Health Administrations of China, Nanking schools and institutes of hygiene, and public health, Hungary, Budapest	9,804.06
Italy, Rome	10,853.93
Japan, Tokyo	27,757.64
University of Brussels, Belgium	247,118.13
	$2,443,179.62

From the above the scope and wide medical affiliations of the Foundation, exemplified in equal measure for work in social and natural sciences, and in the humanities, are easily evident.

* * *

The International Health Division.—In commenting on the work of its International Health Division, the report states:

> The dominant feature of the former world-wide program was the creation and development of technically competent local, state, and national health services. This was the outcome of the still earlier hookworm work, which led to an interest in the formation of well-rounded health departments which would include the control of hookworm disease and similar types of public health work as an integral part of their regular health-protection programs. . . .
>
> The demonstrations in which the Foundation has participated, and the ever-increasing application of present-day methods by governments have undoubtedly greatly extended the benefits of public health service, but at the same time they have brought out, as nothing else could have done, the very real limitations of existing knowledge and particularly its frequent inadequacy when applied to specific problems under special conditions. Through experience it has become apparent that the Foundation can render its greatest service in the public-health field by shifting its emphasis from the rapid and extensive application of existing knowledge to the securing of additional facts necessary to effective and economical control of disease. . . .
>
> The dominant feature of the new program is field research, through which it is hoped to arrive at the control of certain specific diseases. Among the diseases studied in 1935 yellow fever heads the list; malaria, likewise, occupies a position of major importance. Significant contributions were, however, also made in schistosomiasis, yaws, tuberculosis, undulant fever, and other diseases.
>
> The attempt is not made to engage in research on all the diseases in the field of public health. Efforts are concentrated on a limited number of clear-cut public health problems, with emphasis on the need for studies of disease in its environment and on closely related laboratory investigations, in order to define the problems with greater accuracy and to search for more effective and less expensive methods of disease control. . . .

Fifty pages are given to a sketch of activities carried on by the Division of the Medical Sciences, and the following brief excerpts will serve to indicate their nature:

> During 1935 the Rockefeller Foundation appropriated $2,733,050 for work in the field of medical science. Of this sum, $1,459,450 was contributed to projects for the advancement of psychiatry. . . . The term "psychiatry," as used here, is an inclusive one, comprising clinical psychiatry; clinical neurology; the anatomy, physiology, chemistry, pharmacology, and pathology of the nervous system; some aspects of psychology; and those phases of other branches of medicine which bear directly on the understanding of human behavior. . . .
>
> * * *
>
> In six institutions in the United States where circumstances are especially favorable for the development of teaching and research in psychiatry, the Foundation is co-operating in programs to improve the presentation of this subject to medical students and to bring it into closer relation with other branches of medicine. . . .
>
> * * *
>
> Training in psychoanalysis is of great importance to the psychiatrist, but at the present time facilities for such training are limited. To aid in extending opportunities in this field the Foundation made a grant of $100,000 to the Institute for Psychoanalysis, Chicago, payable over a three-year period, beginning October 1, 1935, to enable it to enlarge the scope of its teaching and research. . . .
>
> * * *
>
> In the study of mental diseases, child psychiatry is one of the basic fields to be investigated. . . .
>
> * * *
>
> The School of Medicine of the University of Chicago has been one of the few important medical schools of the United States without a department of psychiatry. Plans to remedy this defect have been under consideration at the University for some time. The possibility of aid for research work from the Sprague Fund has made the project especially attractive. The proposed plans are now being put into effect with the aid of a Rockefeller Foundation grant of $168,000. . . .
>

Other Foundations Might Well Model After the Rockefeller. — The few paragraphs given above are sufficient to indicate the excellence of the major plans of the Rockefeller Foundation and the splendid and efficient manner in which work in all its departments is carried on. In these days, when so many foundations seem to be using their resources on wild-goose chases, it is reassuring to read such an account as that of the Rockefeller. Almost every page of the report is a tribute to the importance of wise and sane management in undertakings of this nature. The administrative heads of some of the other foundations, whose names have graced the pages of lay and scientific press in recent years, and given the impression of having lost their heads somewhat as they visualized their responsibilities, could study this Rockefeller report advantageously. An acceptance of its standards and methods would result in an elimination of some of the vagaries and egotisms which the directors of one or two other foundations seem unable to keep in the background. It would be well for all foundations, massive or otherwise, to keep in mind that man's world has been existing many hundreds of years, and that cultural and welfare developments have not been confined to recent times. Further, that in things closely associated with the daily lives of human beings, something more than revolutionary academic or report dissertations are necessary before the world can be changed.

This truth applies particularly to activities related to medicine, in which such amazing progress has been made in the last half century under a system which some lay theorists are insistent shall be changed to suit their views. Wherefore, as already stated, the 1935 report of the Rockefeller Foundation should be of interest to all medical men. At the next visit to your medical library, ask for the volume. It is well worth a careful inspection.

EDITORIAL COMMENT[†]

THE TECHNIQUE OF ELECTROCARDIOGRAPHY*

It had been known since 1856 that the contraction of the heart resulted in the production of an electrical current, but not until 1887 did Waller demonstrate that this current could be led off from the surface of the body and recorded. Einthoven, in 1904, was the first to perfect an instrument sufficiently sensitive to accurately follow the small, rapidly-varying heart currents, and apparatus to record them.

The earlier instruments were string galvanometers, the sensitive element being a very fine gold-plated quartz fiber suspended between the poles of a powerful electromagnet. Here the heart current, without modification, passes directly through the string and results in the deflection. Lately, instruments using vacuum tubes have been developed which greatly amplify the action current and pass it through the string of a relatively insensitive galvanometer, carrying a small mirror. Here the deflection of a reflected beam of light is photographed. In the string instruments it is the shadow of the string itself which is photographed.

The advantages and disadvantages of the two types of instruments are relative and minor. The string instruments must be more carefully handled, are operated preferably from batteries, are more easily shielded from alternating current interference, and give slightly higher complexes, mostly in the R and T waves, although it is not proven that this is a more accurate picture than that obtained with tube instruments, and the difference is usually slight. The vacuum tube instruments are more portable, usually may be run from 110-volt alternating current lines (ordinary house current), but give more trouble from A. C. base-line interference, and are more prone to have mechanical difficulties. One prime difference is the fact that the skin resistance of the patient has no effect on the vacuum type. In the string instrument it must be compensated for.

Whatever type instrument is used for the actual recording of the electrocardiogram, there are certain precautions to be observed in the preparation of the patient and the actual taking of the picture.

Preparation of Patient.—1. The patient, when he is first informed of the desirability of obtaining an electrocardiogram, should be told that the activity of his heart produces the deflection and there is no possibility of his receiving an electrical shock. This is conducive to mental rest and physical relaxation on the part of the patient, and also results in a much smoother base line on the cardiogram.

2. The patient should be given a slip by his doctor (if forms are not supplied) to take to the cardiographer, giving the age, clinical diagnosis and details as to treatment with digitalis, as minimum information necessary. These facts are of distinct aid to the cardiographer in his interpretation, since his function is more to correlate findings or suggest possibilities than to make a diagnosis (except for disturbances of rhythm).

Technique.—1. The essential conditions are to have the patient in a prone position and at rest. Dyspneic patients should be propped up with sufficient pillows to prevent respiratory embarrassment, as an absolutely horizontal position is not necessary. Just before each lead is taken, the patient should be cautioned to be absolutely quiet, but may be allowed to move or talk at other times.

2. Proper electrical connection of the patient to the apparatus must be made. The skin where the contact is to be made should be scrubbed vigorously with a towel dipped in warm salt solution. The gauze is then soaked in this solution, wrapped about the limb, and the electrode applied tightly over it. These precautions lower skin resistance and prevent skin current.

3. Lead IV connections are made by placing the right arm electrode on the anterior chest wall over the fourth left interspace, just to the left of the sternum. The left arm electrode is placed on the posterior chest wall directly opposite the other electrode. The patient is kept in the semirecum-

San Francisco.

INTERPRETATION OF ELECTROCARDIOGRAMS

Within recent years clinical electrocardiography has come to be more generally used, and it is accepted as an important aid in the diagnosis of cardiac disease. However, its limitations are well recognized by cardiologists. Severe heart disease may not be accompanied by electrocardiographic abnormality and, conversely, definite abnormalities frequently are not inconsistent with good cardiac function. The evaluation of the electrocardiogram, therefore, should always be made in the light of careful clinical examination, and caution should be exercised in the interpretation of electrocardiographic changes.

The electrocardiograph is frequently of great value in clarifying the presence of various arrhythmias. It is sometimes impossible, for example, to distinguish clinically between auricular fibrillation, premature auricular beats and multiple extrasystoles, and similarly, the paroxysmal tachycardias, without its aid.

The presence of myocardial disease is often disclosed when not detectable clinically. It is practically impossible to diagnose latent heart block without electrocardiographic evidence, and this is frequently so with bundle-branch or I-V block. In coronary thrombosis the tracings are often characteristic, but not always necessary to diagnose the condition clinically; on the other hand, in doubtful cases of angina pectoris, typical changes may serve to substantiate the diagnosis definitely.

The electrocardiograph may be of considerable help in the therapeutic management of the cardiac patient, and particularly in detecting the toxic effects of digitalis on the myocardium prior to their clinical manifestations. It furnishes very little information, however, concerning the presence of valvular or congenital heart disease, and then only indirectly.

To estimate accurately the significance of abnormalities in the electrocardiogram, it is essential to know certain physiological principles in regard to the origin and spread of action currents in the normal heart, and likewise to appreciate the variation in appearance and time relation that may normally occur in the complexes. The following are some of the more important criteria employed in the interpretation of electrocardiographic tracings at the University of California Hospital:

NORMAL FIGURES:

Rate 60 to 100 min.

P.R. interval—0.20 sec. or less in lead in which it is longest.

Q.R.S. interval—0.10 sec. or less in lead in which it is longest.

Axis deviation—

- Right—The main deflection of Q.R.S.$_1$ is down and of Q.R.S.$_3$ is up.
- Left—The main deflection of Q.R.S.$_1$ is up and of Q.R.S.$_3$ is down.

Voltage of Q.R.S. complex—usually over 10 mm. in lead showing the highest voltage. Deflections under 5 mm. in all leads are definitely abnormal.

Voltage of T wave—Over 1 mm.

CRITERIA OF BUNDLE-BRANCH BLOCK:

Q.R.S. interval over 0.10 sec.

Q.R.S. complex slurred or notched.

A definite axis deviation with the T wave in opposite direction from main Q.R.S. deflection (sometimes in opposite direction from the slurred limb of the Q.R.S. deflection).

FUNCTIONAL DISTURBANCES GENERALLY ASSOCIATED WITH MYOCARDIAL DAMAGE:

In the conduction system:

- Prolongation of P.R. or Q.R.S. interval (especially in the case of bundle-branch block).
- Definite slurring or notching of Q.R.S. complexes in two leads.

In the muscle:

- Low or inverted T waves (in leads other than III, and providing effects of drugs are ruled out).
- Usually in the case of certain abnormal rhythms, such as auricular fibrillation and flutter and ventricular tachycardia.
- Marked deviations of R.T. or S.T. interval from the base line.
- Deep Q$_3$ (over 25 per cent of height of largest Q.R.S. deflection).

CRITERIA FOR NORMAL LEAD IV (OR V):

P wave small, diphasic or inverted.

Q.R.S. complex diphasic with deep Q wave.

S.T. interval short, sloping into an inverted T wave.

CRITERIA FOR ABNORMAL LEAD IV (OR V):

(*a*) T wave:

1. A positive T wave.
2. A disphasic T wave taller than 2 mm.
3. A shallow broad negative T wave less than ¼ mm. high.
4. A negative T wave deeper than 9 mm.

(*b*) S.T. segment:

1. A positive S.T. segment.
2. A negative S.T. segment more than 2 mm.
3. Any negative S.T. deviation when associated with a positive T wave.

(*c*) Q.R.S. complex:

1. Slurred or notched.
2. Monophasic (absent Q wave).

Any one is considered abnormal, but a combination is of more significance.

Limited space will not permit a complete discussion and illustrations of the differentiation of arrhythmias and the more recent knowledge of evidences of myocardial damage; hence, the reader is referred to the literature on the subject.

BETTER OBSTETRICS*

By Henry A. Stephenson, M.D.
San Francisco

It has long been recognized that the maternal mortality rates in the United States have been higher than those in other civilized countries. While it is difficult to get entirely satisfactory figures for comparison, it has been shown that the mortality rate in the United States is 64 to 67 per ten thousand live births, while in Italy and Sweden it is 26 to 27. These figures represent the highest and lowest rates. It is also a fact that no appreciable improvement in our own rates has been made for several years. Among obstetricians, particularly, there has been systematic inquiry and serious thought regarding the causes for this situation. Unusual interest was aroused by the White House Conference Studies on Prenatal and Maternal Care and Child Health and Protection. That report showed that in the United States birth registration area there are annually 15,000 maternal deaths, about 86,000 stillborn children, and nearly 80,000 dying in the first two weeks of life. In trying to explain the high rate in this country, it is necessary to analyze all of the factors related both to pregnancy and parturition.

BIOLOGIC BACKGROUND OF PREGNANCY

One should consider the biologic material out of which the pregnancy originates. The habits and activities of the individual undoubtedly play an important part in the future offspring. Acute and chronic infection, and constitutional diseases existing at the time of conception cannot but play a rôle in the integrity of the ovum and fetus. Very frequently the physician has little opportunity to advise concerning the preëxisting physical status, as most patients become pregnant before the doctor is consulted.

Mothers who have babies in rapid succession or those who, as a result of frequent pregnancies, indulge in induced abortions, are often not physically fit to withstand the strain of pregnancy and labor, and are more vulnerable to infection. A more tangible group of factors, from the physician's viewpoint, includes toxemias, operations during pregnancy, hospital facilities, induction of labor, the use of analgesics and anesthetics, operative deliveries and postpartum care.

TOXEMIA

The question of toxemia has been so thoroughly discussed and kept before the profession in the past decade that little need be said here except again to urge the importance of prenatal care in the prevention and early detection of these conditions.

DELIVERY IN THE HOME AND HOSPITAL

It is essential to be certain of the facilities one has at his disposal for the care of obstetrical patients. Whether the delivery be in the home or at the hospital, the physician must satisfy himself that he has provided the best available facilities. There has been much argument regarding the relative dangers of delivery in the home and in the hospital. There are ardent supporters of each group. Kosmak showed that increased hospitalization, amounting to 65 per cent of all the deliveries in New York City in the year 1930, has a tendency to increase the amount of operative interference. Stout found, on studying a series of cases, that the incidence of infection was almost twice as great in normal women delivered in the home as in a comparative group delivered in the hospital, 8.4 to 4.6 per cent, respectively; and that there was no difference in the severity of infection in the two groups. His conclusion, then, was that the patient has a better chance of escaping infection in a modern maternity hospital than in her own home. On the other hand, Macchia reviews a thousand home cases delivered without a maternal death. Only nine of these thousand had to be removed to the hospital for delivery. It is difficult to draw definite conclusions from isolated reports such as these, but it seems certain to me that the mother is better safeguarded from obstetrical accidents and emergencies when surrounded by the facilities provided in a well-equipped maternity hospital.

ANALGESICS AND ANESTHETICS

The conduct of labor involving the use of analgesics and anesthetics is largely dependent upon the ability and training of the attendant. The widespread demand for relief from pain, and the fairly universal employment of drugs causing analgesia may increase, somewhat, the risk to both mother and baby. At present restrictions should be placed on the list of drugs used, and the safer and less toxic ones should be selected. The benefit derived from the judicious use of such drugs justifies, to my way of thinking, the increased risk entailed. In my experience, the majority of the patients having such drugs show a more rapid and satisfactory postpartum recovery, and the fetal mortality rate is not affected.

OPERATIVE DELIVERIES

The percentage of operative deliveries is increasing. For many years it has been variously stated as from 5 to 15 per cent. Plass states that it should be around 5 per cent, but most writers have felt this figure to be too conservative. In New York City in 1930-1932 the incidence was 20 per cent, while in Philadelphia in 1931-1933 it was 28 per cent. Dallas of San Francisco reported a series of one thousand consecutive deliveries occurring in private practice during 1929 to 1933, in which operation was done in 62 per cent. In this series, 13.4 per cent were cesarean section. Similar figures for cesarean section are reported in other cities. In the Boston Lying-In

Chairman's address before the Obstetrics and Gynecology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

Hospital in 1929-1930, eight per cent of all deliveries were by cesarean section, while in the Jefferson Hospital in Philadelphia the figure was 16 per cent. The advantages of the low cervical operation have raised the cesarean percentage considerably, but at the same time have almost entirely eliminated the harmful operation of high forceps. Dallas reports only three high-forceps operations in his series. This should reflect favorably on the fetal mortality rates. Plass, in reporting 4,839 cases of death, occurring in thirteen states in 1927, found 2,225 operations, or 46 per cent; and of these, 11 per cent were cesarean sections and 16½ per cent were forceps. In a similar study in 1927 by Adair, Mussey and Holmes, out of 2,500 puerperal deaths there were 1,700 operations; of these, 12 per cent were forceps and 9 per cent cesarean section. These figures may not give a true picture of the incidence and influence of operative deliveries, however, since an analysis was made of only those patients who died. A clearer picture would have been obtained had the entire series of patients delivered been reported. It is probably true that too many operations are done. For many of these there is no justifiable indication, and at times the facilities are inadequate; often the operator is not sufficiently trained. McIlroy expresses the matter superbly when he says that "operations are easy, but decision as to their necessity requires judgment and experience." Kosmak, in reviewing 2,800 cases of labor in primiparae in the Woman's Hospital, New York City, found less damage resulting from so-called prophylactic methods, including low forceps with episiotomy, than from spontaneous deliveries; but he limits the procedure to men adequately trained and to hospitals adequately equipped. This limitation is absolutely essential. Undue importance, then, must not be given to operations as a factor in mortality. Undoubtedly some patients are lost as a result of the operation performed. Many babies and mothers would probably have less morbidity and mortality if the indicated operation was skillfully performed at the proper time. In analyzing the series above reported by Adair, Mussey, and Holmes, the causes of death are given as: sepsis, 41 per cent; toxemia, 23 per cent; and hemorrhage, 11 per cent. These conditions account for 75 per cent of the series. Operations may have been used in the delivery of these patients, but it was not *per se* the principal factor in the tragic outcome.

MORTALITY RATE IN PREGNANCY

The White House Conference on Prenatal and Maternal Care concluded that the high maternal mortality rate of this country is a reflection on the training and education of the personnel responsible for furnishing maternal care. The report of the committee of the New York Medical Society states that 61 per cent of the preventable deaths are the fault of the medical attendant, usually brought about by some incapacity, such as deficient judgment, lack of skill, or carelessness.

HOW CAN EDUCATION BRING ABOUT BETTER OBSTETRICS?

Having set before you the principal factors associated with the present mortality rate in this country, we shall turn to the effect of education in bringing about better obstetrics.

Progress of obstetrical knowledge, rapid in the last few years, has been along four general lines, namely, the development of asepsis, the extension of prenatal care, improvement in operative technique, and the employment of analgesics and anesthetics for the relief of pain. This knowledge is available to every student and medical graduate at the present time. The methods by which it is taught and the application of it by the practitioner will be discussed later in this essay.

PUBLIC SHOULD BE EDUCATED

It is essential that the public itself be educated regarding procreation and its manifold problems. Maxwell has stated that "human genetics and eugenics should be carefully considered in any plan on race betterment ideals." This statement will probably become increasingly important as the public becomes more obstetrically minded. The campaign of education should proceed through agencies of the medical profession, particularly those of the public health. Women should be taught to place themselves promptly under competent medical supervision. The importance of the pre- and postnatal periods should be explained relative to hygiene, diet, and minor ailments in pregnancy; and as to the duties and responsibilities arising in the puerperium.

The widespread and helpful influence of social workers should become more and more felt in preventive medicine. The training and medical supervision of this group should be such that they will become a prominent factor in bringing about education of the public.

LEGAL RECOGNITION OF THE MIDWIFE

Obstetrics is the only branch of medicine which can be legally practiced by persons not having a medical degree. In Europe the midwife is an old-established institution. By law she is controlled as to license and reports including disease notification and births, requirements for calling physicians in emergencies and in complicated cases, and punishment for malpractice. There are only two schools for midwives in America, one in Philadelphia and one in New York. Many states have laws governing midwives, but they are less stringent and less rigidly enforced than in Europe. In the United States, at present, midwives deliver about one patient in six, in some states as many as one in three. In four states, having over 10 per cent of the deliveries attended by midwives, the maternal death rate was the same for doctors and midwives. This finding has been usually explained by the fact that midwives are required to call in physicians in difficult or emergency cases. Frequently these patients are at a stage where ideal treatment cannot be given. The midwife is, at present, a necessity. Better supervision and control will improve her and her work.

PLACE OF THE NURSING PROFESSION IN OBSTETRIC PRACTICE

The nursing profession occupies a high place in rendering a service well-nigh indispensable to the sick. The physician is grateful for its help; but a word must be said regarding nursing education. The requirements of many training schools for nurses have improved so that a better educated type is now being graduated from such institutions; but the educational prerequisites in many schools is still too low. As a result of a survey made in 1930, the conclusion was drawn that many nurses do not understand the meaning of adequate maternity care. It is a fact that many women patients are influenced by the graduate nurse, and it is exceedingly important that she be correctly informed, and that she thoroughly understand the full significance of such advice as she may offer; therefore, special training beyond that offered in the regular nursing curriculum should be given the obstetrical nurse. The opportunities of such a well-trained nurse for communicating obstetrical knowledge to the public are second only to those of the physician.

THE EDUCATION OF THE PHYSICIAN

What has been said above regarding education is certainly most desirable; but it is secondary to the most important factor concerning this entire problem, that is, the education of the doctor. The responsibility for the maternal mortality rate is being placed more and more on the shoulders of the physician. We must recognize the fact that the physician at time of graduation is not qualified to do satisfactory obstetrics any more so than he is to do major or special surgery. Munro Kerr quotes the following recommendation from the report of the Joint Education and Examination Committee of the General Medical Council of Great Britain: "For first, every practitioner must know thoroughly well and in a practical way how to conduct safely a case of labor, particularly a complicated case." The attainment of this result would be ideal. Why does not such a situation exist, and what can be done to bring it about?

TIME ALLOTTED TO OBSTETRICS IN MEDICAL SCHOOLS

The explanation begins with our medical schools. Adair states that the main purpose of undergraduate medical education is the laying of the foundations for a knowledge of medicine on which subsequent structures can be built for general or special practice, and for teaching or research, and for public health activities. This viewpoint is correct, but it is not impressed sufficiently upon the public to enable them always to distinguish between the well and the poorly trained practitioner. Only in recent years has obstetrics been considered a surgical specialty, and has received serious consideration in the arrangement of the curriculum. Too few hours of instruction have been allotted. Since gynecology and obstetrics have been combined in many medical schools, efforts are being made to give these subjects as many hours of instruction as are given to general surgery. Cornell Medical School recently adopted such a program. Allotted hours alone, however, cannot train an obstetrician. The method of teaching and the ability of the teacher are of the utmost importance. Ample clinical facilities are essential. Medical schools should provide sufficient clinical material to fulfill such requirements, or limit the number of students to that justified by the existing material. Lynch found that most medical schools are unable to give their undergraduates cases sufficient in number to demonstrate ordinary complications. Regarding this, it is interesting to note the results of a questionnaire sent by Findley in 1931 to the deans of all schools having a four-year course. To the question, "What is a reasonable number of labors for a student to observe?" there were fifty replies, forty-three stating, "fewer than thirty." To the question, "What is a reasonable number of patients to deliver?" there were fifty-four replies, forty-eight answering, "fewer than twenty," and eighteen answering, "fewer than ten." Only thirty-nine schools had facilities for giving each student as many as twenty deliveries. This gives a fairly accurate idea of the regard in which obstetrics has been held by the deans of our best medical schools. Their opinions are probably influenced by the lack of facilities for providing more training. Even more interesting is the result of a questionnaire addressed to the graduates of the above-mentioned schools. Six were chosen from each school, and were graduated in the years 1921 to 1928. Of 158 questioned regarding the number of patients they had delivered, eighty-one had none in their junior year; eighteen had none in their senior year; and thirteen had none in their interne year. In the same number of graduates, fifty-nine in their junior year delivered fewer than thirty cases; 109 in the senior year delivered fewer than thirty cases; and fifty-one in the interne year delivered fewer than thirty cases. To the query regarding home deliveries, sixty-two of the 158 had done home deliveries without having an instructor present. It seems incredible that the modern medical schools would send out students to deliver women in their homes without having an instructor present. It certainly is not giving the public the kind of obstetrics to which they are entitled.

MANDATORY INTERNE YEAR

Realizing full well, then, that at the end of the medical course the young graduate is not properly qualified or equipped to do satisfactory obstetrics, although legally entitled to do so, what facilities and opportunities are available to further equip him to measure up to Kerr's recommendation? First, let us approve of the required interne year which some schools have adopted. This added year furnishes valuable opportunity to the student to apply, under supervision, knowledge gained in the regular medical course. Opportunities for further improving one's obstetrical knowledge, and acquiring experience, is furnished by hospital residencies. The Council of the American Medical Association has recently made a survey in which they report that in this year 1936 there are available 2,600 residencies in specialties in 405 hospitals. Most of these are for the period of one year. While this length of time is not adequate for the training of a specialist or teacher, nevertheless it will go a long way toward raising the general standard of graduate obstetrical education. In order for such residencies to be of maximum value the hospital concerned should have a competent teaching staff, and should have the work well supervised.

The training of specialists and teachers will not be fully discussed here, as the main purpose of this paper applies to the general practitioner, because we believe that in his hands lies the major responsibility for maternal welfare. The specialist and the consultant are essential, and should be readily available in difficult complications of pregnancy and labor, but their influence should be in the direction of helpful coöperation and teaching. With the means of rapid transportation now available, no physician, however remote he may be from a medical center, need be without the advice and help of a well-trained specialist. The economic problem involved in this last statement will prove somewhat troublesome, but is not beyond satisfactory solution.

POSTGRADUATE COURSES

Many graduates, after becoming established in practice, will not do obstetrics, but many will of necessity or by choice have a variable number of cases. What can be done to continue the education and interest of such practitioners, particularly along practical lines, which will keep them abreast of advances in technique and in treatment? Some medical schools have adopted "refresher" courses, lasting from one to six weeks. These courses, where given, have proved very stimulating and very helpful to those enrolled. They should be carefully planned and given in such a way that the graduates get information and advice which will prove most helpful to them. Care should be exercised in choosing the proper instructor for such courses. He should be a senior staff member who understands the problems of the practitioner, and who has had sufficient clinical experience to speak with authority. Some states have adopted so-called "circuit" courses. By this method a well-trained instructor from a medical school is sent to various communities in the state to give a course of three or four lectures or demonstrations whenever practical. This method is very popular with many practitioners because it does not necessitate leaving their work; it is less formal and results in the development of a better professional spirit. The ability and personality of the instructor determine the success of such a plan. Another effort along educational lines which should be helpful to both profession and public is being made by the American Board of Obstetrics and Gynecology. Its aim is to improve the standards of practice of obstetrics and gynecology, to determine competence of specialists in this branch of medicine, and to serve the public, the hospitals, and the medical schools by preparing lists of practitioners who have been certified by the Board. It may be desirable to consider in the very near future the establishment by legislation of standards qualifying such practitioners and the granting of special certificates or licenses to those who by special training, experience and examination satisfy such requirements. The benefit resulting from such measures as above outlined and recommended would be the establishment of better obstetrical care, ultimately manifesting itself in better protection for the obstetrical patient.

DERMATOLOGY—SOME THOUGHTS ON ITS FUTURE*

By William H. Goeckerman, M.D.
Los Angeles

It has been customary in recent years to take stock and endeavor to visualize the future of medical practice. Some were ready, two or three years ago, to revert to ancient practice and relegate the specialist to a secondary position. In fact, some advocated less preparation for the medical degree. They admitted that this would lower the quality of service, but argued that not all can demand the best. This point of view, no doubt, was brought about in part by the economic conditions of recent years.

NEED FOR SPECIALIZATION

However, there is a surging tide in the evolution of medicine, part of progress if you will, as in all other walks of life, which will not be denied. Your farmer, your housewife, your mechanic—yes, your common day laborer specializes. The whole present-day economic life is built on the principle of specialization. It is true that here and there we still find the practices of a past generation in the arts as well as in medicine, one individual covering his particular field rather thoroughly, sometimes to the decided advantage of the community. In the main, however, it cannot be denied that society is better served by far through an intelligent specialization. Whether such specialization should be intensive will depend upon circumstances. I believe we will all agree, for instance, that the ophthalmologist who devotes intensive study to the fundus, with reference to neurologic and internal medical problems, to the exclusion of surgery and treatment problems of the eye has a field so limited that he must be working under very special conditions. But few could make such a choice advantageously. Herrick has said: "To the brilliant mind of half a century ago a working knowledge of all the departments of medicine was attainable; today such a prodigy is impossible." That is trite today, because even many of the departments of medicine no longer permit proficiency in their entirety. Reasonable specialization under proper conditions is, therefore, eminently justified.

---

* Chairman's address before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

FUTURE OF DERMATOLOGY

With this axiom in mind I should like to place before you some thoughts on the future of our own specialty. It can frankly be stated that our medical colleagues not in the specialty have a very hazy idea of the aims of modern dermatology. With regard to this matter they are still in the "morphologic" era. If only they can give the child a name on the basis of its external characteristics, then some recommended drug and, presto! it is easy or possibly very difficult. As in every other department of medicine, the specialist in dermatology must be endowed with skill, knowledge, and judgment. Few have these qualities in equal degree, and happy is he in whom they are well balanced. Skill can be acquired, as in surgery, by repeating the technical procedure frequently. Often it is the intellectually less gifted but endowed with a mechanical bent who removes superfluous hair, telangiectasia, warts, nevi, most deftly, who uses local anesthesia most cleverly, and who enters a vein and spinal canal most expertly. You all know the old story about the imbecile who is active in a class of backward children. On a given occasion the professor demonstrates this child before a group of students. After pointing out the lack of intelligence, he emphasizes by demonstration the mechanical skill of the child, expands on the desirability of placing this child in a position where such gifts as it has may prove useful. Toward the end of the demonstration he ends with a short quiz, and requests that one of the students briefly outline the occupation such a child might follow. The student, after some hesitation, blurts forth with: "I think he would make a good surgeon." This story is, of course, no longer apropos, but even thirty years ago was not much beside the mark. While a reasonable degree of technical skill is necessary and desirable for the dermatologist, it is, in my opinion, the least important. It is, however, often the individual mechanically inclined who impresses the uncritical patient most favorably. Possibly this accounts for the emphasis often placed upon it.

FUNDAMENTAL KNOWLEDGE NECESSARY

Knowledge in dermatology can be acquired. It does mean, however, close application for a considerable period of time. Genius has been defined as the ability to take infinite pains. While the dermatologist may not be a genius, the true specialist can evolve only by taking infinite pains in close application. This means gathering detail both in theoretical book learning and practical observation. It is detailed knowledge that distinguishes the true specialist. The necessity of close application in gathering detailed knowledge has been demonstrated to me again and again by watching the postgraduate student in our specialty over a considerable number of years. I have seen such students spend three years in daily close contact with dermatologic problems, and at the end of that time be unable to hold their own in a discussion of some question related directly to dermatology. The fault lay in a lack of close application to study and independent thought in the light of such study on the problems encountered daily. Judgment is in part, no doubt, an inherited characteristic. There is a type of mind that never acquires it, even if endowed with a retentive memory and industry. Without knowledge judgment cannot be developed. But knowledge must be well digested before it becomes part of good judgment. In addition to these qualifications the expert in dermatology is fortunate if he is visual-minded, much as the good musician has auditory endowments without which he cannot be a master.

APPROACH MUST BE ALONG MANY LINES

The modern dermatologist thinks essentially in terms of biology, physiology, chemistry, and histopathology. To be sure, gross morphology retains its importance and always will, but it is not by any means enough. A name for a special type of eruption is needed in order that intelligent communication may take place between initiated individuals. Its clinical behavior must be known as far as this is possible. But the approach to treatment can be intelligent only when thought is given also to the details of the histologic picture, to the probability of an infectious, allergic, endocrine, metabolic, toxic, neurogenic, or other background. Many of the cutaneous eruptions are purely symptomatic, and empirical treatment can only be haphazard. Let me briefly explain on the basis of a chronic urticaria what is in my mind. To immediately think of food hypersensitiveness or a multiplicity of skin tests just because allergists in their enthusiasm have not seen the forest for the trees is nonsense, because it is very seldom that food is the causative factor. It is well known that chronic gall-bladder disease, chronic appendicitis, achlorhydria, constipation, thyroid disturbance, chronic infections of various character, neurogenic and psychogenic upsets, etc., are usually responsible. It is apparent then that within certain limits he must have the approach of the internist rather than the allergist. While it may develop that the systemic difficulty should be managed by the internist, the latter is not in position to determine the significance of most cutaneous lesions. I make this statement confidently as the result of close coöperation with good internists for a considerable number of years. I believe I have said enough to emphasize that the expert in dermatology is no longer chiefly a morphologist who gives the disease a name, which to the average medical mind smacks of verbosity. Nor is he primarily a technician whose supreme interest is the deft removal of a wart or mole. In the use of ointments or other applications he does not think only of a name and some favorite drug. He never asks, or at least he never should ask: What do you do for such and such an eruption? Instead he uses his experience and technical accomplishments with intelligence, endeavors to acquire all the knowledge possible on a particular subject, and brings such judgment to bear as his native endowment permits him to acquire. If you agree with me—and those who know the problems of dermatology readily will—you will note that intelligence and learning of the highest order are required in the real expert. In the main, the problems of dermatology are difficult and complex, which no one with real experience will deny.

DERMATOLOGIC PRACTICE NEEDS SPECIALIZATION

In my opinion the physician without special training does not manage cutaneous diseases successfully. Let me call your attention merely to so simple a problem supposedly as scabies. Thus far I have mentioned the qualifications which fit the expert to deal with his clinical problems in the most approved manner. There is another field into which he ventures, with certain reservations justly so. He engages in research. Many have large numbers of tubes filled with culture media, and others even numbers of experimental animals, or chemical apparatus at their disposal. Unless an individual is specially qualified, such interests contribute little of real value to clinical dermatology. The test-tube and the animal are not human, and the reactions and problems are seldom the same. Such research work can well be left to the pure scientist or to those primarily interested in the laboratory. We know only too well that many of their deductions are faulty or not applicable in the human. Of course there can be no objection to a young dermatologist working in this field under supervision. But there is a type of research that should receive better cultivation than it does, and that is clinical research. The importance of this type of research is apparently only slowly regaining the recognition it deserves, not only in dermatology but in medicine in general. I do not refer to the common practice of trying to find one's pet conception whenever possible, or of breaking into print with immature or overenthusiastic observations.

IMPORTANCE OF SCIENTIFIC APPROACH

I would rather emphasize the critical attitude, the uncompromising search after truth, let the result be what it may, the incessant search for flaws in possibly hasty conclusions—in brief, the truly scientific approach. For this purpose a carefully studied clinical case is often more valuable than undigested statistical studies based on laboratory findings. If this form of research involves laboratory problems, the joint approach with a man versed in laboratory practice is desirable. An outstanding example of the form of research I have in mind is the work repeatedly reported on recently by Stokes and Becker. Those of us who have close contact with general medical problems have recognized for many years the importance of the autonomic nervous system in its relation to various dermatoses. If we have failed to do this we no doubt have missed an opportunity to give of our best to the patient. To be sure, this whole problem is in its infancy, but it should have our close critical attention. It is likely that significant progress will only be made as the physiology of the nervous system becomes better known. The vast importance of this problem to us cannot be denied, but as true specialists we should see to it that ridiculous deductions do not creep in, and that the interest in it is not carried to the absurd, as has been done so often with more or less fundamental problems in medicine.

COLLATERAL KNOWLEDGE DESIRABLE

In addition to all these professional qualifications, a thorough grounding in the problems of history, a sagacious understanding of biography, and more than a smattering of philosophy, psychology, and even possibly religion should contribute attributes which make for the finest type of specialism. Such general cultural knowledge makes for a better understanding and management of disease problems even in dermatologic practice.

IN CONCLUSION

The somewhat crude encroachments of other specialties make me wonder particularly just how dermatology will shape itself in the future. The unscientific approach of the so-called allergist, endocrinologist, and radiotherapist to dermatoses will vanish. Such specialists will in time cultivate the field they know something about. Truth will out in these fields as well as in our own and only truth can endure. The old order in our specialty must pass, and in the main it has passed, but most of our confrères not in the specialty still think of it in terms of a hundred years ago. My dissertation was conceived in the thought that we must be physicians first and specialists second rather than only specialists. Not the crusading, but the scientific and judicial attitude must prevail, and this is true whether we are dealing with manifestly cutaneous lesions due to allergy or lesions in which this biologic phenomenon is in no way concerned. It is only in this way that we can retain our proper niche, and the respect and support of the medical profession as a whole. But if we work to this end and show it not only in word but in deed as well, there is no doubt that the specialty will fill a necessity and endure through generations to come.

APRAXIA*

By Samuel D. Ingham, M.D.
Los Angeles

Discussion *by Walter F. Schaller, M.D., San Francisco; J. M. Nielsen, M.D., Los Angeles; Thomas G. Inman, M.D., San Francisco.*

APRAXIA has been described as the inability to perform purposeful movements, not due to paralysis, ataxia, agnosia, or general physical or psychic impairment. It is comparable to the condition of motor aphasia, in which the patient knows what he wants to say, but is unable to express himself. So the apractic, without being paralyzed and knowing the use of objects, is unable to handle them in a normal manner.

LIEPMANN'S CONCEPT OF APRAXIA

The concept of apraxia was developed by Liepmann in 1900 on the basis of a single case. This case presented a marked degree of unilateral apraxia, and offered a remarkable opportunity for analysis. Liepmann not only made an exhaustive clinical study of the patient, but was able to follow the case post-mortem and to determine the brain lesion responsible for the symptoms. Liepmann's work, based on this case, remains today the outstanding contribution to the subject of apraxia, and it was he who first clearly differentiated the functions of the afferent and efferent cerebral association pathways.

EVENTS IN THE PERFORMANCE OF A MOTOR ACT

Since apraxia is a disturbance of an individual's motor reaction to his environment, it is necessary to have a clear understanding of the related processes which are necessary to normal activities. When a person performs a motor act on the request of another, an interesting series of events must occur in the brain of the subject. The sound of the voice is perceived (auditory perception); the words and sentences are recognized (apperception or gnosia); associative memory of related ideations and concepts are stimulated; the idea is evaluated in the affective sphere in regard to its personal significance; a plan of action or response is decided upon (ideational plan); volition directs action in the execution of the ideational plan, and a sequence of appropriate, voluntary, coördinated movements are executed which follow kinetic patterns that have been established by inheritance, experience, and habit. Throughout the entire process of perceiving the sensory impression, elaborating it and acting upon it, consciousness, or an awareness, must be directed by a concentrated and flexible condition of the attention.

Normal motor responses thus depend upon a rather complicated series or sequence of psychological functions. Of these functions the primary sense perception, and the voluntary motor impulse, are effected by cerebral projection tracts, sensory and motor. All of the other items in the series are the work of cerebral association and commissural tracts. By definition, therefore, apraxia must be due to lesions of certain cerebral association tracts relating to ideation and voluntary motion. Incidentally, it may be remarked that the aphasic disturbances of speech result from lesions of cerebral association areas—not projection tracts. Motor aphasia is a special form of apraxia; and word deafness and blindness are agnosias for auditory and visual word symbols. Paraphasias result from disturbances in the ideational fields.

SOME CLINICAL SYMPTOMS RESULTING FROM ORGANIC LESIONS OF THE BRAIN

It is interesting to consider this group of clinical symptoms resulting from organic lesions of the brain which affect the association and commissural tracts in contrast to the more easily recognized symptoms due to involvement of the projection tracts serving the sensory and motor functions. We thus have the agnosias, amnesias, aphasias, apraxias, and hallucinations, which are well established on an organic basis. This brings us close to the concept of localization in the psychoses. Drug intoxications, encephalitis, paresis, and many other clinical pictures show distinct tendencies to exhibit symptoms of agnosia, amnesia, perseveration, temporal and spatial displacements similar to those seen in organic brain disease, and in which there is at least a suggestion of localization. On the other hand, it may be stated, as a general rule, that where organic disease causes agnosias, aphasias and apraxias, there is always some defect of cerebration beyond that implied by the diagnosis.

LIEPMANN'S CASE

Liepmann's famous case started December 1899, with an apoplectiform attack in a man of forty-eight, which resulted in a condition that was diagnosed in two institutions as aphasia with dementia resulting from apoplexy. When the patient came under his observation, two and one-half months after the onset of the condition, Liepmann found a right-sided apraxia and Broca's aphasia. The patient could understand and execute orders by using his left arm when the right was restrained. This proved that he was neither suffering from word deafness nor any high degree of dementia. Movements of the right arm, on the other hand, appeared to be out of control although there was no paralysis or ataxia. He moved the arm freely and movements were well coördinated. He picked up objects, but not the ones he was requested to pick, and he could not imitate movements with the right arm only. In the course of time he learned to adjust himself fairly well by using the left arm for all purposes. The case came to necropsy after about two years. In the meantime, additional vascular accidents causing left hemiplegia had occurred. The patient died in April, 1902.
